About This Guide

The Dual Stack Architecture with IPv6 guide describes ScreenOS support for Internet Protocol version 6 (IPv6) and how to secure IPv6 and IPv4/IPv6 transitional networks with tunneling and IPsec.

Dual-stack architecture allows an interface to operate simultaneously in IPv4 and IPv6 modes and facilitates network management, while a network contains both IPv4 and IPv6 devices that pass traffic between IPv4/IPv6 boundaries.

This guide contains the following sections:

• “Internet Protocol Version 6 Introduction” on page 3 explains IPv6 headers, concepts, and tunneling guidelines.

• “IPv6 Configuration” on page 11 explains how to configure an interface for operation as an IPv6 router or host.

• “Connection and Network Services” on page 35 explains how to configure Dynamic Host Configuration protocol version 6 (DHCPv6), Domain Name Services (DNS), Point-to-Point Protocol over Ethernet (PPPoE), and fragmentation.

• “Static and Dynamic Routing” on page 53 explains how to set up static and dynamic routing. This chapter explains ScreenOS support for Routing Information Protocol-Next Generation (RIPng).

• “Address Translation” on page 81 explains how to use Network Address Translation (NAT) with dynamic IP (DIP) and mapped-IP (MIP) addresses to traverse IPv4/IPv6 boundaries.

• “IPv6 in an IPv4 Environment” on page 95 explains manual and dynamic tunneling.

• “IPsec Tunneling” on page 107 explains how to configure IPsec tunneling to connect dissimilar hosts.

• “IPv6 XAuth User Authentication” on page 127 explains how to configure Remote Authentication Dial In User Service (RADIUS) and IPsec Access Session (IAS) management.

• Switching lists options for using the security device as a switch to pass IPv6 traffic.

• Document Conventions on page xviii
• Document Feedback on page xx
• Requesting Technical Support on page xx
Document Conventions

This document uses the conventions described in the following sections:

- Web User Interface Conventions on page xviii
- Command Line Interface Conventions on page xviii
- Naming Conventions and Character Types on page xix
- Illustration Conventions on page xix

Web User Interface Conventions

The Web user interface (WebUI) contains a navigational path and configuration settings. To enter configuration settings, begin by clicking a menu item in the navigation tree on the left side of the screen. As you proceed, your navigation path appears at the top of the screen, with each page separated by angle brackets.

The following example shows the WebUI path and parameters for defining an address:

Policy > Policy Elements > Addresses > List > New: Enter the following, then click OK:

- Address Name: addr_1
- IP Address/Domain Name:
- IP/Netmask: (select), 10.2.2.5/32
- Zone: Untrust

To open Online Help for configuration settings, click the question mark (?) in the upper right of the screen.

The navigation tree also provides a Help > Config Guide configuration page to help you configure security policies and Internet Protocol Security (IPSec). Select an option from the list, and follow the instructions on the page. Click the ? character in the upper right for Online Help on the Config Guide.

Command Line Interface Conventions

The following conventions are used to present the syntax of command line interface (CLI) commands in text and examples.

In text, commands are in **boldface** type and variables are in *italic* type.

In examples:

- Variables are in *italic* type.
- Anything inside square brackets [ ] is optional.
- Anything inside braces { } is required.
- If there is more than one choice, each choice is separated by a pipe ( | ). For example, the following command means “set the management options for the ethernet1, the ethernet2, or the ethernet3 interface”:
  
  set interface { ethernet1 | ethernet2 | ethernet3 } manage
NOTE: When entering a keyword, you only have to type enough letters to identify the word uniquely. Typing `set adm u whee j12fmt54` will enter the command `set admin user wheezer j12fmt54`. However, all the commands documented in this guide are presented in their entirety.

### Naming Conventions and Character Types

ScreenOS employs the following conventions regarding the names of objects—such as addresses, admin users, auth servers, IKE gateways, virtual systems, VPN tunnels, and zones—defined in ScreenOS configurations:

- If a name string includes one or more spaces, the entire string must be enclosed within double quotes; for example:
  ```
  set address trust "local LAN" 10.1.1.0/24
  ```

- Any leading spaces or trailing text within a set of double quotes are trimmed; for example, `" local LAN "` becomes `"local LAN"`.

- Multiple consecutive spaces are treated as a single space.

- Name strings are case-sensitive, although many CLI keywords are case-insensitive. For example, `"local LAN"` is different from `"local lan"`.

ScreenOS supports the following character types:

- Single-byte character sets (SBCS) and multiple-byte character sets (MBCS). Examples of SBCS are ASCII, European, and Hebrew. Examples of MBCS—also referred to as double-byte character sets (DBCS)—are Chinese, Korean, and Japanese.

- ASCII characters from 32 (0x20 in hexadecimals) to 255 (0xff), except double quotes (`"`), which have special significance as an indicator of the beginning or end of a name string that includes spaces.

NOTE: A console connection only supports SBCS. The WebUI supports both SBCS and MBCS, depending on the character sets that your browser supports.

Document Feedback

If you find any errors or omissions in this document, contact Juniper Networks at techpubs-comments@juniper.net.

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or JNASC support contract, or are covered under warranty, and need postsales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the JTAC User Guide located at http://www.juniper.net/customers/support/downloads/710059.pdf.
- Product warranties—For product warranty information, visit http://www.juniper.net/support/warranty/.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.
Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings—http://www.juniper.net/customers/support/
- Find product documentation—http://www.juniper.net/techpubs/
- Find solutions and answer questions using our Knowledge Base—http://kb.juniper.net/
- Download the latest versions of software and review your release notes—http://www.juniper.net/customers/csc/software/
- Search technical bulletins for relevant hardware and software notifications—http://www.juniper.net/alerts/
- Join and participate in the Juniper Networks Community Forum—http://www.juniper.net/company/communities/
- Open a case online in the CSC Case Manager—http://www.juniper.net/customers/cm/
- To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool—https://tools.juniper.net/SerialNumberEntitlementSearch/

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Manager tool in the CSC at http://www.juniper.net/customers/cm/.
- Call 1-888-314-JTAC (1-888-314-5822—toll free in USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, visit us at http://www.juniper.net/customers/support/requesting-support/.

CHAPTER 1

Internet Protocol Version 6 Introduction

ScreenOS supports Internet Protocol version 6 (IPv6), developed by the Internet Engineering Task Force (IETF).

NOTE: Some security devices support IPv6. Check the datasheet for your security platform to determine which features it supports.

This chapter contains the following sections:

• Overview on page 3
• IPv6 Addressing on page 4
• IPv6 Headers on page 6
• IPv6 Packet Handling on page 8
• IPv6 Router and Host Modes on page 9
• IPv6 Tunneling Guidelines on page 9

Overview

By using addressing and schema that are different from IPv4, IPv6 allows a greater number of connected hosts than IPv4 can allow. In addition, IPv6 reduces packet processing overhead and increases network scalability. Together, these improvements allow a greater exchange of data traffic.

IPv6 provides for interoperability between IPv4 devices and IPv6 devices. It is usually possible to install IPv6 on security devices without losing IPv4 capability, so organizations can perform incremental upgrades and avoid service disruptions while migrating from IPv4 to IPv6.

NOTE: For more information about IPv6, refer to RFC 2460.

ScreenOS features dual-stack architecture, which allows an interface to operate simultaneously in IPv4 and IPv6 modes. Dual-stack architecture allows you to secure your network infrastructure while it contains both IPv4 and IPv6 devices and to secure traffic that passes across IPv4/IPv6 boundaries.
Each IPv6-enabled security device can operate as an IPv6 host or router.

IPv6 Addressing

IPv6 addresses differ from IPv4 addresses in several ways:

- Notation
- Prefixes
- Address Types

These differences give IPv6 addressing greater simplicity and scalability than IPv4 addressing.

Notation

IPv6 addresses are 128 bits long (expressed as 32 hexadecimal numbers) and consists of eight colon-delimited sections. Each section contains 2 bytes, and each byte is expressed as a hexadecimal number from 0 to FF.

An IPv6 address looks like this:

2080:0000:0000:0000:0008:0800:200c:417a

By omitting the leading zeroes from each section or substituting contiguous sections that contain zeroes with a double colon, you can write the example address as:

2080::8:800:200c:417a or 2080::8:800:200c:417a

For example, 0000:0000:0000:0000:0000:0000:0000:0000:93fc:9303 can be written as::93fc:9303.

You can use the double-colon delimiter only once within a single IPv6 address. For example, you cannot express the IPv6 address 32af::ea34:0:71ff:fe01 as 32af::ea34::71ff:fe01.

Prefixes

Each IPv6 address contains bits that identify a network and a node or interface. An IPv6 prefix is the portion of an IPv6 address that identifies the network. The prefix length is a positive integer that denotes a number of consecutive bits, beginning with the most significant (left-most) bit. The prefix length follows a forward slash and, in most cases, identifies the portion of the address owned by an organization. All remaining bits (up to the right-most bit) represent individual nodes or interfaces.

For example, 32f1::250:af:34ff:fe26/64 has a prefix length of 64.

The first 64 bits of this address are the prefix (32f1:0000:0000:0000). The rest (250:af:34ff:fe26) identifies the interface.

Address Types

RFC 2373 describes three major categories of IPv6 addresses:
• Unicast
• Anycast
• Multicast

Unicast Addresses

A unicast address is an identifier for a single interface. When a network device sends a packet to a unicast address, the packet goes only to the specific interface identified by that address.

Devices use the following types of unicast addresses:

• A global unicast address is a unique IPv6 address assigned to a host interface. Global unicast addresses serve essentially the same purposes as IPv4 public addresses. Global unicast addresses are aggregatable for efficient and hierarchical addressing.

• A 6to4 address enables an IPv6 host interface for 6to4 tunneling. A 6to4 interface can serve as a border router between the host and IPv4 network space. In most cases, this method is not suitable for performing IPsec operations such as authentication and encryption.

• A link-local IPv6 address allows communication between neighboring hosts that reside on the same link. The device automatically generates a link-local address for each configured IPv6 interface.

• An IPv4-mapped address is a special IPv6 address that is the equivalent of an IPv4 address. A device uses IPv4-mapped addresses for address translation, when the device must send traffic from an IPv6 network to an IPv4 network.

Anycast Addresses

An anycast address is an identifier for a set of interfaces, which typically belongs to different nodes. When a network device sends a packet to an anycast address, the packet goes to one of the interfaces identified by that address. The routing protocol used in the network usually determines which interface is physically closest within the set of anycast addresses and routes the packet along the shortest path to its destination.

For more information about anycast addresses, refer to RFC 2526.

Multicast Addresses

A multicast address is an identifier for a set of interfaces, which typically belongs to different nodes. When a network device sends a packet to a multicast address, the device broadcasts the packet to all interfaces identified by that address.

Devices use the following types of multicast addresses:

• Solicited-node multicast addresses for Neighbor Solicitation (NS) messages.
• All-nodes multicast address for Router Advertisement (RA) messages.
• All-routers multicast address for Router Solicitation (RS) messages.
IPv6 Headers

The IETF designed IPv6 headers for low overhead and scalability. IPv6 headers allow optional extension headers, which contain extra information usable by network devices.

Basic Header

Every IPv6 packet has a basic IPv6 header. IPv6 headers occupy 40 bytes (320 bits). Figure 2 on page 6 shows each field, arranged in order.

Figure 2: Header Structure

<table>
<thead>
<tr>
<th>Bit Length</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Version</td>
</tr>
<tr>
<td>8</td>
<td>Traffic Class</td>
</tr>
<tr>
<td>20</td>
<td>Flow Label</td>
</tr>
<tr>
<td>16</td>
<td>Payload Length</td>
</tr>
<tr>
<td>8</td>
<td>Next Header</td>
</tr>
<tr>
<td>128</td>
<td>Source IP Address</td>
</tr>
<tr>
<td>128</td>
<td>Destination IP Address</td>
</tr>
</tbody>
</table>

Table 1 on page 6 lists the fields with bit lengths and their purposes.

Table 1: IPv6 Header Fields, Length, and Purpose

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Bit Length</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>4</td>
<td>Specifies the Internet Protocol used by the header and packet. This value tells destination internet devices which IP stack (IPv4 or IPv6) to use when processing the packet header and payload. IPv6 Version fields contain a value of 6. (IPv4 Version fields contain a value of 4.)</td>
</tr>
<tr>
<td>Traffic Class</td>
<td>8</td>
<td>Allows source nodes or routers to identify different classes (or priorities) of IPv6 packets. (This field replaces the IPv4 Type of Service field, which identified categories of packet transfer services.)</td>
</tr>
<tr>
<td>Flow Label</td>
<td>20</td>
<td>Identifies the flow to which the packet belongs. Packets in a flow share a common purpose, or belong to a common category, as interpreted by external devices such as routers or destination hosts. Typically, the source host inserts Flow Label values into outgoing packets to request special handling by the external devices. The external devices can uniquely identify each flow by evaluating the source address in combination with the Flow Label value. Traffic transmitted by a source host can contain packets in a single flow, multiple flows, no flow, or any combination. (Packets that do not belong to a flow carry a Flow Label of zero.)</td>
</tr>
<tr>
<td>Payload Length</td>
<td>6</td>
<td>Specifies the length of the IPv6 packet payload, expressed in octets.</td>
</tr>
<tr>
<td>Next Header</td>
<td>8</td>
<td>Identifies the type of IP protocol for the header that immediately follows the IPv6 header. This protocol can be one of two types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• An IPv6 extension header. For example, if the device performs IPsec security on exchanged packets, the Next Header value is probably 50 (ESP extension header) or 51 (AH extension header). Extension headers are optional.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• An upper-layer Protocol Data Unit (PDU). For example, the Next Header value could be 6 (for TCP), 17 (for UDP), or 58 (for ICMPv6). The Next Header field replaces the IPv4 Protocol field. It is an optional field.</td>
</tr>
</tbody>
</table>
Table 1: IPv6 Header Fields, Length, and Purpose (continued)

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Bit Length</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hop Limit</td>
<td>8</td>
<td>Specifies the maximum number of hops the packet can make after transmission from the host device. When the Hop Limit value is zero, the device drops the packet and generates an error message. (This field is similar to the Time to Live IPv4 field.)</td>
</tr>
<tr>
<td>Source IP Address</td>
<td>128</td>
<td>Identifies the host device that generated the IPv6 packet.</td>
</tr>
<tr>
<td>Destination IP Address</td>
<td>128</td>
<td>Identifies the intended recipient of the IPv6 packet.</td>
</tr>
</tbody>
</table>

Extension Headers

Extension headers contain supplementary information used by network devices (such as routers, switches, and endpoint hosts) to decide how to direct or process an IPv6 packet. The length of each extension header is an integer multiple of eight octets. This allows subsequent extension headers to use 8-octet structures.

Any header followed by an extension header contains a Next Header value that identifies the extension header type.

Extension headers always follow the basic IPv6 header in order as follows:

1. The Hop-by-Hop Options header specifies delivery parameters at each hop on the path to the destination host. When a packet uses this header, the Next Header value of the previous header (the basic IPv6 header) must be 0.

2. The Destination Options header specifies packet delivery parameters for either intermediate destination devices or the final destination host. When a packet uses this header, the Next Header value of the previous header must be 60.

3. The Routing header defines strict source routing and loose source routing for the packet. (With strict source routing, each intermediate destination device must be a single hop away. With loose source routing, intermediate destination devices can be one or more hops away.) When an packet uses this header, the Next Header value of the previous header must be 43.

The firewall can block packets that have a routing header of type 0. To avoid blocking all routing headers, configure the routing header type filters using the following command: set service <name>protocol routing-ext-hdr type<value>.

4. The Fragment header specifies how to perform IPv6 fragmentation and reassembly services. When a packet uses this header, the Next Header value of the previous header must be 44.

5. The Authentication header provides authentication, data integrity, and anti-replay protection. When a packet uses this header, the Next Header value of the previous header must be 51.

6. The Encapsulating Security Payload header provides data confidentiality, data authentication, and anti-replay protection for encapsulated security payload (ESP).
packets. When a packet uses this header, the Next Header value of the previous header must be 50.

7. To filter or deny the extension header with a user-defined service, define the src-port and dst-port as wildcard 0-65535.

### IPv6 Packet Handling

An interface configured for dual-stack operation provides both IPv4 and IPv6 capability. Such an interface can have an IPv4 address, at least one IPv6 address, or both.

If the interface resides at the boundary between an IPv4 network and an IPv6 network, the device can pass IP traffic over the boundary in one of two ways:

- Encapsulate (effectively hiding) any packet that passes across the boundary.
- Perform address translation on the packet source and destination addresses.

Figure 3 on page 8 shows a packet-handling flow that might occur when an IPv6 host passes an outgoing service request packet across the IPv6/IPv4 boundary into an IPv4 network space.

**Figure 3: Packet Flow Across IPv6/IPv4 Boundary**

1. An IPv6 host transmits a service request packet. The source and destination addresses use IPv6 format.
2. IPv6 interface ethernet1 receives the packet.
3. The security device applies a policy to the packet. It either encapsulates the entire packet inside an IPv4 packet or translates the addresses to IPv4 format.
4. IPv4 interface ethernet3 transmits the packet (now using IPv4 address format).
5. A remote gateway node receives the packet.
   - If encapsulation occurred, the device might de-encapsulate the packet or continue to treat it as an IPv4 packet.
   - If IPv6/IPv4 address translation occurred, the device might translate the addresses back to IPv6 format or continue to treat the packet as an IPv4 packet.
IPv6 Router and Host Modes

You can configure each interface in a security device to function as an IPv6 host or router.

- In host mode, the interface functions as an IPv6 host and autoconfigures itself by requesting and accepting Router Advertisement (RA) messages from other devices.
- In router mode, the interface functions as an IPv6 router. An IPv6 router replies to Router Solicitation (RS) messages from IPv6 hosts by sending RAs. In addition, the interface can broadcast RAs periodically or in response to configuration changes to keep the on-link hosts updated.

IPv6 Tunneling Guidelines

Before deciding which kind of tunneling to use, ask your upstream ISP which IPv6 services they provide and how they provide them. We recommend the following guidelines:

- If your ISP provides only dual-stack IPv6, which is Internet Protocol Control Protocol (IPCP) and IPv6CP, you should configure run dual-stack, native IPv6. 6to4 addressing format is not appropriate in this case.
- If your ISP provides manual tunnel IPv6 (IPv6-over-IPv4 tunnel), you should use manual tunneling.
- If your ISP does not provide IPv6, go to www.hexago.com/ to find an upstream IPv6 provider, and follow their posted instructions.

For updates and service information about IPv6, visit one of the following websites:

- http://www.ipv6day.org/
- http://www.ipv6tf.org/
- http://www.ipv6forum.com/

NOTE: The above references are provided as effective resources as of the publication date of this document. However, we encourage administrators to seek out their own IPv6 references, which might be more current.

If you do not find an IPv6 provider, use 6to4 tunneling. This option, however, is only feasible if the next-hop router is configured for it.
CHAPTER 2

IPv6 Configuration

This chapter explains how to enable IPv6 features on the security device and how to configure the security device to act as an Internet Protocol version 6 (IPv6) router or IPv6 host.

This chapter contains the following sections:

• Overview on page 11
• Enabling an IPv6 Environment on page 18
• Configuring an IPv6 Host on page 19
• Configuring an IPv6 Router on page 21
• Viewing IPv6 Interface Parameters on page 30
• Multicast Listener Discovery Protocol on page 31
• Configuration Examples on page 33

Overview

ScreenOS allows you to configure a security device to be an IPv6 router or an IPv6 host.

This overview explains the following topics:

• Address autoconfiguration
• Neighbor discovery

The sections following the overview explain how to configure an IPv6 host or router.

Address Autoconfiguration

Address autoconfiguration allows local hosts to autoconfigure IPv6 addresses from their extended unique identifier (EUI) values. A security device configured for address autoconfiguration advertises an IPv6 prefix to local IPv6 hosts. The local hosts use this prefix to autoconfigure IPv6 addresses from their EUI values.

Address autoconfiguration reduces the need to manually assign addresses to individual hosts. Ideally, IPv6 hosts have address autoconfiguration enabled. An interface, configured to operate as an IPv6 router, can enable local on-link IPv6 hosts to perform autoconfiguration. Autoconfiguration does not require a stateful configuration protocol, such as Dynamic Host Configuration Protocol version 6 (DHCPv6).
Extended Unique Identifier

An EUI address is a 64-bit hex interface identifier. If you do not specify an EUI value explicitly, the security device autogenerates it from the MAC address of the IPv6 interface. This usually happens immediately the first time you define an IPv6 interface.

A device configured for address autoconfiguration advertises an IPv6 prefix to local IPv6 hosts. The local hosts use this prefix to autoconfigure IPv6 addresses from their EUI-ID values.

**NOTE:** For more information about EUI, refer to Guidelines for 64-Bit Global Identifier (EUI-64) Registration Authority at [http://standards.ieee.org/regauth/oui/tutorials/EUI64.html](http://standards.ieee.org/regauth/oui/tutorials/EUI64.html)

Router Advertisement Messages

A Router Advertisement (RA) is a message sent by a router to on-link hosts periodically or in response to a Router Solicitation (RS) request from another host. The autoconfiguration information in an RA includes the following:

- IPv6 prefixes of the IPv6 router, which allow the on-link hosts to access the router
- Maximum Transmission Unit (MTU), which informs the on-link hosts the maximum size (in bytes) of exchanged packets
- Specific routes to the router, which allow the on-link hosts to send packets through the router
- Whether or not to perform IPv6 address autoconfiguration and, when appropriate, a prefix list
- Period that autoconfigured addresses remain valid and preferred

Router Solicitation Messages

A Router Solicitation (RS) is a message sent by hosts to discover the presence and properties of on-link routers. When an IPv6 router receives an RS request from a host, it responds by transmitting an RA message back to the host. An RA announces the existence of the router and provides the host with the information it needs to perform autoconfiguration tasks.

Each RS contains the link-local address of the source host. The host derives the link-local address from its MAC address. When the IPv6 router receives the RS, it uses the link-local address to transmit an RA back to the host.

Prefix Lists

A prefix list is a table containing IPv6 prefixes. When entries are present in the list, the router includes them in the RAs it sends to on-link hosts. Each time a host receives an RA, it can use the prefixes to perform address autoconfiguration. Figure 4 on page 13
shows Host A and Host B using three prefixes to generate unique global aggregatable addresses.

Figure 4: Address Autoconfiguration

1. On startup, IPv6 Hosts A and B generate link-local addresses from their MAC addresses.
2. Each host broadcasts RS messages. Each message uses the host link-local address as the source address for the RS packets.
3. The IPv6 router receives the RS message.
4. The IPv6 router transmits confirming RA messages to the hosts. These messages contain a prefix list.
5. The hosts use the prefixes to perform autoconfiguration.

Neighbor Discovery

Neighbor Discovery (ND) is the process of tracking the reachability status for neighbors in a local link. A device views a neighbor as reachable when the device receives recent confirmation that the neighbor received and processed IP traffic or Neighbor Solicitation (NS) requests. Otherwise, it considers the neighbor unreachable. Although not explicitly required, IPv6 host might have ND enabled. An IPv6 router with ND enabled can send ND information downstream.

Neighbor Cache Table

The Neighbor Cache table contains information about neighbors to which hosts have recently sent traffic. In addition, the table tracks the current reachability status of neighbors on the local link. Each entry contains the following information:

- IPv6 address of the neighbor
- MAC address of the neighbor
- Current neighbor reachability state
- Age of the neighbor entry
- Number of packets currently queued for transmission to the destination neighbor
Table entries are keyed on the IPv6 address. All entries are synced to the backup device in an NSRP cluster. When device failover occurs, the backup device becomes the primary and sends the NDP packet to the neighbor host to notify it of the change.

**Neighbor Unreachability Detection**

Neighbor Unreachability Detection (NUD) works by building and maintaining a Neighbor Cache table, which contains the address for each neighbor to which a host has recently sent traffic. The device uses these entries to record changes in the reachability status of the neighbors. NUD allows the device to track the changing reachability state of each neighbor and to make traffic-forwarding decisions.

**Neighbor Entry Categories**

A Neighbor Cache table entry can belong to any of four categories. The category of the entry determines how the device generates the entry initially and manages reachability states thereafter.

- **Endpoint host entries:** When an endpoint host makes an initial attempt to send traffic to a neighbor, the device automatically generates a corresponding entry in the Neighbor Cache table. The device uses this entry for further communication and to track the reachability state of the endpoint host.

- **Next-hop gateway router entries:** When you create a virtual routing table entry in a device for a gateway router, the device automatically generates a corresponding entry in the Neighbor Cache table. The device uses this entry for further communication and to track the reachability state of the gateway router.

- **Manual tunnel gateway interface entries:** When you set up a manual IPv6 over IPv4 tunnel interface, the device automatically generates an entry for the interface. This entry has an IPv6 link-local address. The device uses this entry to monitor the reachability state of the tunnel.
  - For information about IPv6 over IPv4 tunneling, see “IPsec 6in4 Tunneling” on page 115.
  - For information about link-local addresses, see “Configuring Manual Tunneling” on page 96.
  - For information about tunnel gateway transitions, see “Tunnel Gateway State Transitions” on page 17.

- **Static entries:** When you create a Neighbor Cache entry statically, the device does not use it to perform ND or NUD operations. Instead, it assigns the entry a special reachability state called Static. This enables the entry in all circumstances. While the entry exists, the device forwards any traffic sent to the represented neighbor.

**Neighbor Reachability States**

No Neighbor Cache entry exists for a neighbor until the device sends the neighbor an initial NS request. Until this happens, the device does not recognize the existence of the neighbor. When the device sends the initial request, it creates a table entry and sets it to the Incomplete state.

The reachability states are as follows:
- **Incomplete**: A host attempted to send traffic to a neighbor currently unknown to the device, and initial address resolution is still in progress. The device broadcasts an NS request (using a solicited node multicast address) to find the neighbor, but has not yet received a confirming Neighbor Advertisement (NA).

  The incomplete state has different characteristics when the neighbor is a next-hop gateway router. For more information, see “Next-Hop Gateway Router State Transitions” on page 16.

- **Reachable**: The device currently considers the neighbor reachable because it received a confirming NA reply from the neighbor. While the entry state is Reachable, the device forwards any traffic sent to the neighbor. The entry state remains Reachable until the Reachable Time interval (expressed in seconds) elapses. Then the state changes to Stale.

- **Stale**: The device considers the neighbor unreachable because the Reachable Time interval has elapsed since the most recent NA from the neighbor. However, the device makes no attempt to verify reachability until a host attempts to send more traffic to the neighbor.

- **Delay**: A host attempted to send traffic to the neighbor while the state was Stale. The device makes no active attempt to verify neighbor reachability. Instead, it waits for upper-layer protocols to provide reachability confirmation. The device maintains the Delay state for five seconds. If the device receives confirmation during this delay period, the state changes to Reachable. Otherwise, the state changes to Probe.

- **Probe**: The Delay period elapsed, and the device received no confirmation from the upper-layer application. The device sends up to two unicast NS probes to verify reachability. If the device receives an NA message from the neighbor, the state changes to Reachable. Otherwise, the device deletes the reachability entry from the table. In effect, removal of a neighbor entry makes the device view the neighbor as nonexistent.

- **Probe Forever**: The device no longer considers the neighbor reachable, has made an attempt to forward traffic to the neighbor, and is sending unicast NS probes to verify reachability. The device continues to retransmit the probes indefinitely or until it receives a reachability confirmation from the neighbor.

  The device uses the Probe Forever reachability state only when the entry represents a next-hop gateway router.

  **NOTE:** The Neighbor Cache entry might also exist in Active and Inactive states but only when the neighbor is a manual IPv6in4 tunnel gateway interface.

---

**How Reachability State Transitions Occur**

A device changes the reachability state of a Neighbor Cache entry depending on the neighbor category, the current state of the entry, and whether on-link hosts attempt to send traffic to the neighbor.
**Endpoint Host State Transitions**

When an on-link host attempts to send traffic to a neighbor, the device searches the Neighbor Cache table for a corresponding Neighbor Cache table entry. If no entry exists, the device broadcasts an NS message for the neighbor. It then creates a new table entry and assigns it an Incomplete state.

Figure 5 on page 16 shows how the device handles reachability state transitions after it generates a Neighbor Cache entry.

**Next-Hop Gateway Router State Transitions**

When you create a routing table entry to an IPv6 next-hop gateway router, the device automatically generates a corresponding Neighbor Cache table entry and assigns it an Incomplete state.

Figure 6 on page 17 shows how the device handles reachability state transitions after it generates the Neighbor Cache entry for the first time.
When you remove a router from which the device generated a Neighbor Cache table entry, the device deletes the entry automatically.

**Tunnel Gateway State Transitions**

When you configure an interface for manual IPv6-in-IPv4 tunneling, the device automatically generates a corresponding entry in the Neighbor Cache table.

A device uses two entry states (also known as heartbeat states).

- **Inactive**: The device does not consider the neighbor reachable and has sent an NS message to test for reachability.
- **Active**: The device considers the neighbor reachable and periodically sends NS messages to confirm reachability.

When you create the IPv6-over-IPv4 tunnel, the device generates the Neighbor Cache entry and assigns it the Inactive state. Figure 7 on page 18 shows how the device handles reachability state transitions after initial generation of the entry.
When you remove the manual tunnel from which the device generated the Neighbor Cache Table entry, the device deletes the entry automatically.

For information about manual IPv6 over IPv4 tunneling, see “IPsec Tunneling” on page 107.

**Static Entry Transitions**

When you create a static entry, the device always forwards traffic transmitted to the neighbor because no NUD operations apply.

**Enabling an IPv6 Environment**

To set up a security device for IPv6 operation, you must first enable an IPv6 environment variable on the device. You must complete this step otherwise you cannot view IPv6 features or options in the WebUI or the CLI.

**Enabling IPv6 at the Device Level**

To enable IPv6, you must start a CLI session with the device. You can establish CLI sessions using software that emulates a VT100 terminal, such as Telnet or Secure Command Shell (SSH). If you make a direct connection through the console port, you can use HyperTerminal. (For more information about establishing CLI sessions, refer to the installation and configuration guide for the security device.

To check the IPv6 status of the security device, enter the following command:

```
get envar
```

If the device is currently IPv6-enabled, the following appears in the console output:

```
ipv6=yes
```

If this output does not appear, the device is not IPv6-enabled (default). To enable IPv6, enter the following commands:
set env ipv6=yes
save
reset save-config yes
When the confirmation prompt appears, enter y.

Disabling IPv6 at the Device Level
You must start a CLI session with the device by establishing a console connection with HyperTerminal or another terminal emulation software.
To disable IPv6, enter the following commands:
unset env ipv6
save
reset
When the confirmation prompt appears, enter y.

Configuring an IPv6 Host
After enabling the device for IPv6 operation, you can configure the device to be an IPv6 host by performing the following steps:
1. Bind the interface to a zone (such as Trust, Untrust, or a user-defined zone).
2. Enable the mode and interface.
3. Configure address autoconfiguration.
The following sections describe ScreenOS settings pertinent to IPv6 host configuration.

NOTE: Optionally, in addition to an IPv6 address, the security device can have an IPv4 IP address associated with the same interface. For information about IPv4 interface configuration, see Fundamentals.

Binding the IPv6 Interface to a Zone
You can bind an interface to a custom or preset security zone with the WebUI or the CLI. Interface naming varies by platform. To view the interfaces on your security device you can use the get interface command.
In the following example, you bind an interface named ethernet1/2 to the trust zone.

WebUI
Network > Interfaces: Select Edit to change the zone binding for an existing interface entry or click New to configure a new interface entry.

CLI
set interface ethernet1/2 zone trust
save
Enabling IPv6 Host Mode

You can enable IPv6 modes from the WebUI or the CLI. The mode options are: none (not using IPv6), host, or router.

**WebUI**

Network > Interfaces: Select *Edit* to change the IPv6 mode for an existing interface entry or click *New* to configure a new interface entry. Select *Host* mode.

Network > Interfaces > Edit (for ethernet1) > IPv6

**CLI**

```
set interface ethernet1/2 ipv6 mode host
set interface ethernet1/2 ipv6 enable
save
```

Setting an Interface Identifier

You can configure the Extended Unique Identifier (EUI) for the interface. The EUI is a 64-bit hexadecimal extension of the Ethernet Media Access Control (MAC) address. The device uses this value to autoconfigure an IPv6 link-local IP address for the interface.

**WebUI**

Network > Interfaces: Select *Edit* to change the zone binding for an existing interface entry, or click *New* to configure a new interface entry. Enter an *Interface ID*.

**CLI**

```
set interface ethernet1/2 ipv6 interface-id 0210dbfffe7ac108
save
```

Configuring Address Autoconfiguration

When you define a prefix list entry for address autoconfiguration, IPv6 on-link hosts can use the prefix to generate unique IPv6 addresses. In the following example, you define prefix list entry 2bfc::0/64.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface) > Prefix lists: Enter the following, then click *OK*:

- New IPV6 Prefix/Length: 2bfc::0/64
- Prefix Flags
  - Autonomous: (select)
  - Onlink (select)

**CLI**

```
set interface ethernet3 ipv6 ra prefix 2bfc::0/64 autonomous onlink
save
```

After you make this setting, the device automatically includes the prefix in any Router Advertisement (RA) messages sent to on-link hosts.
Configuring Neighbor Discovery

To direct the interface to discover the existence and identity of other routers, you can enable the Accept Incoming RAs setting for the IPv6 interface. With this setting enabled, the interface accepts RA messages from other IPv6 peer devices.

WebUI

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click OK:

Accept Incoming Router Advertisements: (select)

CLI

set interface ethernet3 ipv6 ra accept

After you enable this setting, the interface accepts any route advertisement it receives from another host in the link. When the interface receives such an advertisement, it stores the advertised IPv6 address and MAC address in the Neighbor Cache table.

To see if the interface received and stored any advertised routes, you can view the contents of the NDP table by executing the following command:

get ndp

Configuring an IPv6 Router

To configure an IPv6 router, perform the following steps:

1. Enable the IPv6 environment on the device.
2. Bind the interface to a zone (such as Trust, Untrust, or a user-defined zone).
3. Enable the mode and interface.
4. Configure address autoconfiguration.
5. Configure Router Advertisement (RA) parameters.
6. Configure Neighbor Discovery (ND) parameters.

The following sections describe ScreenOS settings pertinent to IPv6 router configuration.

NOTE: Optionally, in addition to an IPv6 address, the security device can have an IPv4 address associated with the same interface. For information about IPv4 interface configuration, see Fundamentals.

Binding the IPv6 Interface to a Zone

You can bind an interface to a custom or preset security zone with the WebUI or the CLI. Interface naming varies by platform.

In the following example, you bind an interface named ethernet1/2 to the trust zone.
WebUI

Network > Interfaces: Select **Edit** to change the zone binding for an existing interface entry or click **New** to configure a new interface entry.

CLI

interface ethernet1/2 zone trust
save

Enabling IPv6 Router Mode

You can enable IPv6 modes from the WebUI or the CLI. The mode options are: none (not using IPv6), host, or router.

WebUI

Network > Interfaces: Select **Edit** to change the IPv6 mode for an existing interface entry or click **New** to configure a new interface entry. Select **Router** mode.

Network > Interfaces > Edit (for ethernet1) > IPv6

CLI

set interface ethernet1/2 ipv6 mode router
set interface ethernet1/2 ipv6 enable
save

Setting an Interface Identifier

An IPv6 interface identifier sets the Extended Unique Identifier (EUI) for the interface. The EUI is a 64-bit hexadecimal extension of the Ethernet Media Access Control (MAC) address. The device uses this value to autoconfigure an IPv6 link-local IP address for the interface.

WebUI

Network > Interfaces: Select **Edit** to change the zone binding for an existing interface entry, or click **New** to configure a new interface entry. Enter an **Interface ID**.

CLI

set interface ethernet1/2 ipv6 interface-id 0210dbfffe7ac108
save

Setting Address Autoconfiguration

To set host autoconfiguration for an IPv6 router, you must do all of the following settings:

- Enable the Outgoing Router Advertisements.
- Disable the Managed Configuration Flag.
- Disable the Other Parameters Configuration Flag.
Outgoing Router Advertisements Flag

Enabling the Outgoing Router Advertisements flag allows the interface to send Router Advertisement (RA) messages to on-link hosts. After enabling this setting, the interface immediately broadcasts a route advertisement to hosts in the link. It also broadcasts an RA automatically when it receives a Router Solicitation (RS) from a host or when you change any RA setting on the interface.

In the following example, you enable the Allow RA Transmission setting.

WebUI

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click OK:

Allow RA Transmission: (select)

CLI

set interface ethernet3 ipv6 ra transmit

Managed Configuration Flag

Enabling the Managed Configuration flag directs local hosts to use a stateful address autoconfiguration protocol, such as DHCPv6, to generate host addresses.

Local hosts cannot perform stateless address autoconfiguration while this setting is enabled.

In the following example, you disable the Managed Configuration flag to allow autoconfiguration.

WebUI

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click OK:

Managed Configuration Flag: (deselect)

CLI

unset interface ethernet3 ipv6 ra managed

Other Parameters Configuration Flag

Enabling the Other Parameters Configuration flag directs local hosts to use a stateful address autoconfiguration protocol (DHCPv6) to configure parameters other than host addresses.

Local hosts cannot perform stateless address autoconfiguration while this setting is enabled.

In the following example, you disable the Other Parameters Configuration flag to allow autoconfiguration.

WebUI

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click OK:
Other Parameters Configuration Flag: (deselect)

**CLI**

unset interface ethernet3 ipv6 ra other

### Disabling Address Autoconfiguration

To disable host autoconfiguration for an IPv6 router, you must do the following:

- Disable the Outgoing Router Advertisements setting so that on-link host can’t send router advertisements.
- Enable the Managed Configuration Flag to force the hosts to use a stateful addressing protocol, such as DHCPv6.
- Enable the Other Parameters Configuration Flag.

In the following example, you disable address autoconfiguration on an IPv6 router.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- Allow RA Transmission: (deselect)
- Managed Configuration Flag: (select)
- Other Parameters Configuration Flag: (select)

**CLI**

unset interface ethernet3 ipv6 ra transmit
set interface ethernet3 ipv6 ra managed
set interface ethernet3 ipv6 ra other

### Setting Advertising Time Intervals

Address autoconfiguration uses several advertised time interval parameters for IPv6 routers. These intervals determine the frequency of events or the lifetime of identified objects.

**Advertised Reachable Time Interval**

Enabling the Reachable Time setting instructs the interface to include the Reachable Time interval in outgoing RA messages. This interval tells on-link hosts how long in seconds to consider the IPv6 interface reachable after they receive an RA from the interface.

The interface bases the Reachable Time interval on the current Base Reachable Time setting. For information about the Base Reachable Time, see “Base Reachable Time” on page 29.

The interface uses this value while performing Neighbor Unreachability Detection (NUD). The security device builds and maintains a Neighbor Cache table, which contains the address for each neighbor to which a host has recently sent traffic. The device uses these entries to record changes in the reachability status of the neighbors. NUD allows the
device to track the changing reachability state of each neighbor and to make traffic-forwarding decisions accordingly.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

Reachable Time: (select)

**CLI**

```
set interface ethernet3 ipv6 ra reachable-time
```

**Advertised Retransmit Time Interval**

Enabling the Retransmission Time instructs the interface to include the Retransmission Time interval in outgoing RA messages. This interval (expressed in seconds) is the time that elapses between retransmissions of NS messages.

For information about the Retransmission Time interval, see “Retransmission Time” on page 30.

The interface uses this value while performing NUD.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

Retransmission Time: (select)

**CLI**

```
set interface ethernet3 ipv6 ra retransmit-time
```

**Maximum Advertisement Interval**

The Maximum Advertisement interval specifies the maximum number of seconds allowed between transmission of unsolicited multicast RAs from the IPv6 interface.

In the following example, you set the interval to 500 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

Maximum Advertisement Interval: 500

**CLI**

```
set interface ethernet3 ipv6 ra max-adv-int 500
```

**Minimum Advertisement Interval**

The Minimum Advertisement interval setting specifies the minimum number of seconds allowed between transmission of unsolicited multicast RAs from the IPv6 interface.

In the following example, you set the interval to 100 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**: 
Minimum Advertisement Interval: 100

**CLI**

    set interface ethernet3 ipv6 ra min-adv-int 100

**Advertised Default Router Lifetime**

The Default Router Lifetime setting specifies the number of seconds that hosts can identify the interface to be the default router, after the hosts receive the last RA from the interface.

In the following example, you set the lifetime to 1500 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Minimum Advertisement Interval:** 1500

**CLI**

    set interface ethernet3 ipv6 ra default-life-time 1500

**Advertising Packet Characteristics**

An RA can provide on-link host devices with information about packets exchanged through the IPv6 interface, including the link MTU and the hop limit.

**Link MTU Value**

Enabling the Link MTU flag directs the IPv6 interface to include the Link MTU field in RA messages. The Link MTU is the maximum size (in bytes) of any IPv6 packet sent by a host over a link.

**NOTE:** The default Link MTU value for Ethernet is 1500 bytes. The default for PPPoE is 1490 bytes. This value must be from 1280 to 1500. You can change the MTU value for some platforms. Refer to the documentation for your security device to see if you can configure the MTU value.

In the following example, you enable advertisement of the link MTU.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Link MTU:** (select)

**CLI**

    set interface ethernet3 ipv6 ra link-mtu

**Current Hop Limit**

The Current Hop Limit setting specifies the hop limit for packets sent by any local IPv6 host that uses RAs from this interface for address autoconfiguration. Setting the Current Hop Limit value to zero denotes an unspecified number of hops.
In the following example, you set the Current Hop Limit value to 50 hops.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Current Hop Limit**: 50

**CLI**

```
set interface ethernet3 ipv6 ra hop-limit 50
```

**Advertising Router Characteristics**

An IPv6 interface can use RAs to inform on-link hosts of router attributes, including the Link Layer (MAC) address of the interface and the router preference level.

**Link Layer Address Setting**

Enabling the Link Layer Address flag directs the IPv6 interface to include the Link Layer (MAC) address of the interface in outgoing RA messages.

In the following example, you enable the Link Layer Address flag.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Link Layer Address**: (select)

**CLI**

```
set interface ethernet3 ipv6 ra link-address
```

**Advertised Router Preference**

The Advertised Router Preference setting specifies the preference level for the router.

When a host receives the RA from the IPv6 interface, and other IPv6 routers are present, the preference level determines whether the host views the interface as a primary router or a secondary router.

In the following example, you set the preference to **High**, which designates the interface as the primary router.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Advertised Router Preference**: High (select)

**CLI**

```
set interface ethernet3 ipv6 ra preference high
```

**Configuring Neighbor Discovery Parameters**

When you configure an interface for IPv6 operation, the interface must locate and confirm the existence of neighbors on the same link as the interface. Neighbor Discovery (ND) allows a device to track the reachability status for neighbors in a local link.
Neighbor Unreachability Detection

Enabling Neighbor Unreachability Detection (NUD) directs the interface to perform NUD. Each entry in the table represents a neighbor and contains the current reachability status of the neighbor.

In the following example, you enable NUD for IPv6 interface ethernet3.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- NUD (Neighbor Unreachability Detection): (select)

**CLI**

- `set interface ethernet3 ipv6 nd nud`

MAC Session-Caching

By default, the interface uses MAC address session-caching to increase the speed and efficiency of address resolution. Enabling the always-on-dest setting instructs the interface to bypass this process. Before transmitting traffic to a neighbor, the interface always consults the Neighbor Cache table instead of caching the MAC address in the session.

To bypass MAC session caching, enter the following CLI command:

- `set ndp always-on-dest`

Static Neighbor Cache Entries

To create a static entry in the Neighbor Cache table, set the NDP (Neighbor Discovery Parameter) using the CLI command `set ndp`.

- `set ndp ip_addr mac_addr interface`

where:

- `ip_addr` is the neighbor IPv6 address.
- `mac_addr` is the neighbor MAC address.
- `interface` is the device interface.

In the following example, you start a new entry in the Neighbor Cache table.

- Neighbor IP address 32f1::250:af:34ff:fe27
- MAC address 1234abcd1234
- Device interface ethernet3

- `set ndp 32f1::250:af:34ff:fe27 1234abcd1234 ethernet3`

To delete the entry, enter the `unset ndp ip_addr interface` command.
Base Reachable Time

When an IPv6 interface transmits a Neighbor Solicitation (NS) message to a neighbor and receives a Neighbor Advertisement (NA) message in reply, the device sets the neighbor reachability status to Reachable. The Base Reachable Time setting specifies the approximate length of time (expressed in seconds) that the interface maintains the Reachable status.

After this time interval passes, the status goes to stale mode.

**NOTE:** The Base Reachable Time setting only specifies an approximation of the actual time that the status remains Reachable. The exact time interval is called Reachable Time. The interface determines Reachable Time randomly, using the Base Reachable Time as a baseline value. The resulting Reachable Time is usually within 50 to 150 percent of the Base Reachable Time setting.

In the following example, you set the Base Reachable Time (for IPv6 interface ethernet3) to 45 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

Base Reachable Time: 45

**CLI**

```
set interface ethernet3 ipv6 nd base-reachable-time 45
```

Probe Time

While an entry status is Incomplete or Probe Forever (as when the neighbor is a next-hop gateway), the interface attempts to confirm the reachability of the neighbor. Each attempt is called a **probe**. During a probe, the interface transmits NS requests to the neighbor. The endpoint host state mode Probe Time setting specifies the interval of time (expressed in seconds) between probes.

In the following example, you set the Probe Time (for IPv6 interface ethernet3) to 3 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

Retransmission Time: 3

**CLI**

```
set interface ethernet3 ipv6 nd probe-time 3
```
**Retransmission Time**

When an IPv6 interface begins a probe, it transmits NS requests to the neighbor. The Retransmission Time setting specifies the time interval (expressed in seconds) that elapses between NS requests.

The following example sets the Retransmission Time (for IPv6 interface ethernet3) to 2 seconds.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **Retransmission Time**: 2

**CLI**

```
set interface ethernet3 ipv6 nd retransmit-time 2
```

**Duplicate Address Detection Retry Count**

Duplicate Address Detection (DAD) determines if more than one on-link device has the same unicast address. The DAD Retry Count setting specifies the number of consecutive NS messages to send while performing DAD for the IPv6 interface.

The following example sets the DAD Retry Count (for IPv6 interface ethernet3) to 2 retries.

**WebUI**

Network > Interfaces > Edit (for IPv6 interface): Enter the following, then click **OK**:

- **DAD (Duplicate Address Detection) Retry Count**: 2

**CLI**

```
set interface ethernet3 ipv6 nd dad-count 2
```

**Viewing IPv6 Interface Parameters**

To view IPv6 configuration information:

**WebUI**

Network > Interfaces > IPv6

**CLI**

```
get interface
```

**Viewing Neighbor Discovery Configurations**

You can view the current Neighbor Discovery (ND) settings using the WebUI or the CLI. The following example displays the current ND settings for an IPv6 interface (ethernet3).

**WebUI**

Network > Interfaces > Edit (for IPv6 interface)
Viewing the Current RA Configuration

Before configuring an IPv6 interface to function as an IPv6 router, we recommend that you check the current RA configuration.

In the following example, you display the RA configuration settings for IPv6 interface ethernet3.

WebUI
Network > Interfaces > Edit (for IPv6 interface ethernet3): View the current settings.

CLI

geth interface ethernet3 ipv6 ra

Multicast Listener Discovery Protocol

Multicasting is the process of sending information to a set of interested listeners on a specific multicast address. The set of hosts or clients that listen on a specific multicast address is called a multicast group. Multicast traffic is sent to a single multicast address, and host computers that belong to the multicast group receive the traffic that is sent to the group's address.

An IPv6 router uses the Multicast Listener Discovery (MLD) protocol to discover the presence of multicast listeners (clients) on its directly attached links and to specifically learn which multicast address they are interested in joining by sending MLD messages. MLD messages are used within the network segment to exchange membership status information between the router and the hosts. Table 2 describes the types of MLD messages.

Table 2: Multicast Listener Discovery (MLD) Messages

<table>
<thead>
<tr>
<th>MLD message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast Listener Query</td>
<td>Sent by a multicast router to request or poll for group membership from the clients in a network segment.</td>
</tr>
<tr>
<td>Multicast Listener Report</td>
<td>Sent by a client in response to an MLD Multicast Listener Query sent by a multicast router.</td>
</tr>
<tr>
<td>Multicast Listener Done</td>
<td>Sent by a client when it is not interested in joining the multicast group.</td>
</tr>
</tbody>
</table>

To enable MLD on an interface.
WebUI

Network > Interfaces > Edit: Click MLD
MLD: (select)
MLD enable: (select)

CLI

set interface interface-name protocol MLD enable

By default, every MLD-enabled interface will support host mode. If the interface is in IPv6 router mode, the interface acts as an MLD router also. In this way the MLD interface acts in both host and router mode at the same time.

To support the MLD functionality, the ScreenOS security device will act as both the multicast client and multicast router. As a multicast router, the security device sends periodical MLD query packets on IPv6 interfaces to poll for group members. As a multicast client it sends multicast listener report to all MLD enabled interfaces, specifying the multicast address the nodes are interested in joining.

Table 3 describes the IPv6 multicast addresses currently supported by ScreenOS:

### Table 3: Multicast Address

<table>
<thead>
<tr>
<th>Address</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFO2::2</td>
<td>Link local scope routers</td>
</tr>
<tr>
<td>FFO2::1</td>
<td>Link local scope hosts</td>
</tr>
<tr>
<td>FF02:0:0:0:0:1:FFXX:XXXX</td>
<td>Solicited node multicast address</td>
</tr>
</tbody>
</table>

The multicast client sends an MLD multicast listener report to the multicast router in the following three situations:

- When an interface changes its state from DOWN to UP it sends a report to the multicast router specifying all the multicast addresses it is interested in listening to on that particular segment.
- When a security device sends a Multicast Listener Query, the client sends an MLD multicast listener report to the router specifying all the multicast address it is listening to.
- When an unicast or anycast address of the interface is changed, the device sends an unsolicited report for a solicited node multicast address.

You can view MLD information related to an interface and to a multicast group by using the `get mld interface interface-name` command and `get mld group group address` command, respectively.

To clear information and statistics of groups in router mode interface:

```
clear mld interface interface-name [ group group-address | statistics ]
```
Configuration Examples

This section contains examples of IPv6 router and host configuration. Only CLI commands are shown.

IPv6 Router

This example shows a security device with two interfaces that operate in IPv6 router mode:

**CLI**

```plaintext
set interface ethernet2 zone trust
set interface ethernet2 ipv6 mode router
set interface ethernet2 ipv6 enable
set interface ethernet2 ipv6 interface-id 1111111111111111
set interface ethernet2 ipv6 ip 2eee::1/64
set interface ethernet2 ipv6 ra transmit
set interface ethernet3 zone trust
set interface ethernet3 ipv6 mode router
set interface ethernet3 ipv6 enable
set interface ethernet3 ipv6 interface-id 2222222222222222
set interface ethernet3 ipv6 ip 3eee::1/64
set interface ethernet3 ipv6 ra transmit
```

IPv6 Host

This following commands configure an IPv6 host:

**CLI (Device B)**

```plaintext
set interface ethernet2 zone trust
set interface ethernet2 ip 20.1.1.2/24
set interface ethernet2 ipv6 mode host
set interface ethernet2 ipv6 enable
set interface ethernet2 ipv6 interface-id 3333333333333333
set interface ethernet2 ipv6 ra accept
```
This chapter explains the following network and connection services:

- Dynamic Host Configuration Protocol version 6 (DHCPv6)
- Domain Name System (DNS)
- Point-to-Point over Ethernet (PPPoE)
- Fragmentation

The next sections provide an overview of each network or connection service.

**Dynamic Host Configuration Protocol Version 6**

An IPv6 router can only be a DHCPv6 server. An IPv6 host can only be a DHCP client.

As a DHCPv6 client, the interface can request (from a DHCPv6 server):

- Delegation of long-lived prefixes across an administrative boundary. The server does not have to know the topology of the targeted local network. For example, an ISP can use DHCPv6 to assign prefixes to downstream networks through downstream DHCP clients. To speed up the client/server interaction, the client can request rapid commit (if enabled). Rapid commit reduces the number of messages from four to two.
NOTE: For more information about the impact of using rapid commit options, refer to RFCs 3315 and 3633.

- IP addresses of available DNS servers. The interface can also request DNS search-list information. This list contains partial domain names, which assist DNS searches by concatenating entered usernames to the domain names.

As a DHCPv6 server, the interface can provide both of these services to a DHCPv6 client. To speed up prefix delegation, an IPv6 router configured to be a DHCPv6 server can support a rapid commit option. You can also set a server preference option.

NOTE: DHCPv6 is complementary to address autoconfiguration. The services are not interchangeable.

**Device-Unique Identification**

A Device-Unique Identification (DUID) identifies a network device such as a host or a router. You can use the DUID (or a name associated with the DUID) to determine how the device performs prefix delegation for a particular router or host that has a particular DUID.

**Identity Association Prefix Delegation-Identification**

An Identity Association Prefix Delegation-Identification (IAPD-ID) is a positive integer that identifies a certain prefix on the server. The client can use this value to request a specific prefix from the server. If you specify a nonzero IAPD-ID value, it maps statically to a single prefix that has the same IAPD-ID on the server. If you specify a zero IAPD-ID value or omit the value (which assigns it a zero value by default) the IAPD-ID maps it dynamically to a pool of prefixes on the server. The device treats all prefixes with a zero IAPD-ID as belonging to this pool.

A DHCPv6 server can contain up to 16 prefixes per client DUID.

**Prefix Features**

Prefixes delegated by a DHCPv6 server contain the following elements:

- The Top-Level Aggregator (TLA) identifies the highest level in the routing hierarchy (the left most portion of the IPv6 address). The TLA usually specifies owned address space for an organization, such as an ISP. You specify the length of the TLA using the prefix length.

- The Site-Local Aggregator (SLA) identifies a network or subnet used by the organization.

For example, a server might delegate the following prefix:

2001:908e:1::/48

where:
TLA is 2001:908e
SLA is 1

The same server might also delegate the following prefix:

2001:908e:2::/48

where:

• TLA is 2001:908e
• SLA is 2

The SLAs differ in each example, which means that each prefix maps to a different network but belongs to the same owned address space.

Server Preference

You can optionally send a server preference value in the DHCP advertise messages that the device sends to DHCPv6 clients. A DHCPv6 client uses this value to choose one server instead of another.

The default value is –1 and indicates that no preference appears in the advertise messages sent to clients. You can set the value from 0 (lowest priority) to 255 (highest priority).

In the following example, you set the server preference for interface ethernet1/2 to 255, the highest priority.

WebUI

Network > DHCPV6 > Edit (Server): Enter 255 in the Server Preference Number field, then click Apply.

CLI

```
set interface ethernet1/2 dhcp6 server preference 255
```

Dynamic IPv6 Prefix and DNS Information Update

In some cases, a CPE router acting as both a DHCPv6 client and a PPPoE client is configured to negotiate IPv6 prefixes and DNS information for the downstream DHCPv6 server on the other interface of the same CPE router.

In Figure 9 on page 38, for example, the CPE router acts as a DHCPv6 and PPP/PPPoE client on ethernet0/0 and as a DHCPv6 server on bgroup0. It initiates PPPoE connection through ethernet0/0 to request IPv6 prefixes and DNS information from the upstream DHCPv6 server. The learned prefix and DNS information are updated to the downstream DHCPv6 server on bgroup0 of the same CPE router. If the PPPoE connection is disconnected and then reestablished, the IPv6 prefix and the DNS information on the upstream DHCPv6 server will be changed. The CPE router cannot update this information on the downstream DHCPv6 server on bgroup0 unless the already delegated prefix expires. To avoid this, ScreenOS supports dynamic IPv6 prefix and DNS information updates so that the CPE router is not required to wait until the delegated prefix expires.
to renew the information on the downstream DHCPv6 server. This feature is also supported on Ethernet and PPP connections.

Figure 9: CPE Router Acting As Both DHCPv6 Client and PPPoE Client

Configuring a DHCPv6 Server

In environments, such as an ISP, where you allow end users access to outside networks, you can set up security devices to delegate different prefixes with different SLAs. Figure 10 on page 39 shows an upstream IPv6 router set to delegate DHCPv6 prefixes to downstream routers.

The IPv6 router delegates two prefixes, each with a different SLA. Downstream CPE routers are able to use the two different SLAs to assign prefixes to two different networks.
In this example, you configure interface ethernet3 as a DHCPv6 server and specify two prefixes on the upstream ISP router. The prefixes are then available for delegation to a downstream Customer Premises Equipment (CPE) router.

- Specifies downstream client DUID 00:03:00:01:aa:bb:cc:dd:ee:ff. This allows the client to request prefix delegation from the server.

- Delegates the following prefixes:
  - 2001:908e:abcd:a::/64, SLA 1, IAPD 110, preferred lifetime 259200 seconds, valid lifetime 345600 seconds
  - 2001:908e:abcd:b::/64, SLA 2, IAPD 201, preferred lifetime 172800 seconds, valid lifetime 345600 seconds

- Because of the nonzero IAPD numbers, the server delegates both prefixes statically (not dynamically).

**NOTE:** The WebUI section lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

### WebUI

1. **Server Interface**
   - Network > Interfaces > Edit (for ethernet3) > IPv6
   - Network > DHCPV6 > Edit (for ethernet3)

2. **Downstream Client Identification**
   - Network > DHCPV6 > DUID/Prefix Delegation List (for ethernet3) > New DUID

3. **Delegated Prefixes**
   - Network > DHCPV6 > DUID/Prefix Delegation List (for ethernet3) > Add Prefix Entry

### CLI

1. **Server Interface**
set interface ethernet3 ipv6 mode router
defines the interface as a router mode
set interface ethernet3 ipv6 enable
defines the interface as IPv6 enabled
set interface ethernet3 dhcp6 server
defines the interface as a DHCPv6 server

2. Downstream Client Identification
set interface ethernet3 dhcp6 server options client-duid 00:03:00:01:aa:bb:cc:dd:ee:ff

3. Delegated Prefixes
set interface ethernet3 dhcp6 server options pd duid 00:03:00:01:aa:bb:cc:dd:ee:ff
   iapd-id 110 prefix 2001:908e:abcd:a::/64 259200 345600
set interface ethernet3 dhcp6 server options pd duid 00:03:00:01:aa:bb:cc:dd:ee:ff
   iapd-id 201 prefix 2001:908e:abcd:b::/64 172800 345600
save

Configuring a DHCPv6 Client

In the following example, you configure a downstream CPE router to be a DHCPv6 client. The router can then request prefixes from the upstream router, and automatically push IPv6 addresses derived from the prefixes to local hosts. See Figure 10 on page 39.

• Specifies preferred server with DUID 00:03:00:01:11:22:33:44:55:66
• Requests the following preferred prefixes from the server:
  • 2001:908e:abcd:a::/64, SLA 1, IAPD 110, preferred lifetime 259200 seconds (3 days), valid lifetime 345600 seconds (4 days)
  • 2001:908e:abcd:b::/64, SLA 2, IAPD 201, preferred lifetime 172800 seconds (2 days), valid lifetime 345600 seconds (4 days)
• Designates ethernet3 and ethernet4 as downstream interfaces.
  • Prefixes with SLA of 1 go to ethernet3
  • Prefixes with SLA of 2 go to ethernet4

NOTE: The WebUI section lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

WebUI

1. Downstream CPE Interfaces
   Network > Interfaces > Edit (for ethernet4)
   Network > Interfaces > Edit (for ethernet4) > IPv6
   Network > Interfaces > Edit (for ethernet3)
   Network > Interfaces > Edit (for ethernet3) > IPv6
2. Client Interface (to Upstream Router)
   Network > Interfaces > Edit (for ethernet2)
Network > Interfaces > Edit (for ethernet2) > IPv6
Network > DHCPv6 > Edit (for ethernet2)

3. **Preferred Prefixes (from Upstream Router)**
   Network > DHCPv6 > Prefix Assignment List (for ethernet2) >
   Learned (Suggested) Prefix add

4. **Downstream Interfaces**
   Network > DHCPv6 > Prefix Assignment List (for ethernet2) > Prefix Distribution add

---

**CLI**

1. **Downstream CPE Interfaces**
   
   set interface ethernet4 zone trust
   set interface ethernet4 ipv6 mode router
   set interface ethernet4 ipv6 enable
   set interface ethernet3 zone trust
   set interface ethernet3 ipv6 mode router
   set interface ethernet3 ipv6 enable

2. **Client Interface (to Upstream Router)**
   
   set interface ethernet2 ipv6 mode host
   set interface ethernet2 ipv6 enable
   set interface ethernet2 dhcp6 client
   set interface ethernet2 dhcp6 client options request pd
   set interface ethernet2 dhcp6 client prefer-server 00:03:00:01:11:22:33:44:55:66

3. **Preferred Prefixes (from Upstream Router)**
   
   set interface ethernet2 dhcp6 client pd iapd-id 110 prefix 2001:908e:abcd:a::/64 259200
   345600
   set interface ethernet2 dhcp6 client pd iapd-id 201 prefix 2001:908e:abcd:b::/64 172800
   345600

4. **Downstream Interfaces**
   
   set interface ethernet2 dhcp6 client pd iapd-id 110 ra-interface ethernet3 sla-id 1 sla-len 2
   set interface ethernet2 dhcp6 client pd iapd-id 201 ra-interface ethernet4 sla-id 2 sla-len 2
   set interface ethernet2 dhcp6 client enable
   save

---

**Configuring DHCPv6 Relay Agent**

When a DHCPv6 client sends a message to a DHCPv6 server that is not attached to the same link as the client, a DHCPv6 relay agent configured on the client's link will relay the messages between the client and the server. You can configure up to three servers for a relay agent. The relay agent unicasts each message from the client to all three servers at the same time.
You can set up the relay agent on any interface that has an IPv6 address and is in router mode. The following sections explain the steps involved in configuring a DHCPv6 relay agent on the device.

Setting up a DHCPv6 relay agent

1. Enable IPv6:
   ```
   set env ipv6=yes
   ```
2. Reset the security device.
3. Enable IPv6 on interface1:
   ```
   set interface interface1 ipv6 mode router
   set interface interface1 ipv6 ip ipv6 address/num
   ```

Setting up DHCPv6 relay

You can set up the DHCPv6 relay with the WebUI or CLI:

**WebUI:**

1. **Enable the DHCPv6 relay:**
   
   Network>DHCPv6
   
   DHCP Relay Agent: (Select)

2. **Setting Up Server IP Addresses:**
   
   Relay agent Server IP: Enter the server IP addresses to which the relay agent has to relay the messages in the respective fields.

**CLI**

1. **Enable the DHCPv6 relay:**
   ```
   set interface interface1 dhcp6 relay enable
   ```
2. **Setting Up Server IP Addresses:**
   ```
   set interface interface1 dhcp6 relay server-ip IPv6 Address
   ```
Relay Agent Behavior

A relay agent relays messages from the client to the server and also relays Relay-Forward messages from other relay agents.

When a relay agent receives a message to be relayed, it constructs a Relay-Forward message to be sent to the server. The following table defines the fields in a Relay-Forward message:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg-type</td>
<td>RELAY-FORW</td>
</tr>
<tr>
<td>hop-count</td>
<td>Number of relay agents that have relayed this message.</td>
</tr>
<tr>
<td>link-address</td>
<td>Address used by the server to identify the link on which the client is located.</td>
</tr>
<tr>
<td>peer-address</td>
<td>The address of the client or relay agent from which the message to be relayed was received.</td>
</tr>
</tbody>
</table>

The Relay-Forward message includes a Relay Message option to relay messages either to the server or to other relay agent. In addition to this, the relay agent can include an Interface-id option in the Relay-Forward message, to identify the interface on which the client message was received. The server will include this interface-id option in its Relay-Reply message.

When the client sends a message to the relay agent, the relay agent will fill the link address field of the Relay-Forward message with the address of the client’s interface from which the message was received. It sets the hop-count value in the Relay-Forward message to 0. The link-address is used by the server to identify the link on which the client is located.

When the relay agent receives a Relay-Forward message from another relay agent, it copies the source address of the client, which it extracts from the IP datagram into the peer-address field in the Relay-Forward message. It also sets the hop count value to the value of hop count field in the received message incremented by 1.

**NOTE:** If the message received by the relay agent is a Relay-Forward message and the hop count in the message is greater than or equal to the HOP_COUNT_LIMIT, the relay agent will discard the received message.

Server Behavior

When a server receives a Relay-Forward message, it sends a Relay-Reply message to the relay agent containing a response message to the client. The relay agent relays the response message to the client. The following table defines the fields in a Relay-Reply message:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg-type</td>
<td>RELAY-REPL</td>
</tr>
</tbody>
</table>
The Relay-Reply message includes a Relay Message option to relay messages to the relay agent. The server encapsulates the client message as an option in the Relay-Reply message, which the relay agent extracts and relays to the client.

If more than one relay agent was involved when sending the Relay-Forward message to the server, the server follows the exact path when returning the response message to the client. The server creates a Relay-Reply message that includes a Relay Message option containing the message for the next relay agent in return path to the client. That Relay-Reply message contains another Relay Message option to be sent to the next relay agent and so on. The server records the contents in the peer address fields of the received messages and constructs Relay reply messages carrying the response from the server.

NOTE: The DHCPv6 servers should be able to identify the two types of messages. They should respond to the Relay-forward messages and discard the Relay-reply messages.

Both the relay agent and server supports two specific options:

- Relay Message
- Interface ID

These two options appear only in the Relay-forward and Relay-reply messages.

Relay Message Option

In a Relay-Forward message, the Relay Message option carries the message received from the client and relays it verbatim to the next relay or the server.

In a Relay-Reply message the Relay Message option carries the message to be copied and relayed to the relay agent or client whose address is in the peer-address field of the Relay-Reply message.

Interface-ID option

Interface-id option is an optional value that can be sent by the relay agent to identify the interface on which the client message was received. The server copies the Interface-Id option from the Relay-Forward message into the Relay-Reply message and sends it to the relay agent in response to the Relay-Forward message.

Viewing DHCPv6 settings

You can view DHCPv6 relay agent settings from the command line interface. To view DHCPv6 relay settings:

get interface interface_name dhcp6 relay
Sample output:

device-> get interface e0/3 dhcp6 relay
DHCPv6 Configuration, enabled.

<table>
<thead>
<tr>
<th>Mode</th>
<th>relay</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface-id</td>
<td>enabled</td>
</tr>
<tr>
<td>Server-ip list</td>
<td>3000::217:cbff:feff:e307/48</td>

</tr>
<tr>
<td></td>
<td>3003::f21:cbff:feff:521/48</td>
</tr>
</tbody>
</table>

Viewing DHCPv6 Settings

You can view DHCPv6 server and client settings from the command line interface.

To view DHCPv6 settings:

get interface interface_name dhcp6

Sample output:

device-> get interface ethernet1/2 dhcp6
DHCPv6 Configuration, enabled.

<table>
<thead>
<tr>
<th>Mode</th>
<th>server</th>

</tbody>
</table>

Configuring Domain Name System Servers

In order to use Domain Name System (DNS) for domain name-to-address resolution, you must configure the device by entering an IP address for a primary and secondary DNS server. The DNS servers you choose to configure might use IPv4 or IPv6 addresses.

Figure 12 on page 45 shows a primary and secondary DNS server in the Untrust zone behind a router.

Figure 12: Domain Name System Servers

In the following example, you designate an IPv6 server as the primary server and an IPv4 server as the secondary server.

- Primary server residing at IPv6 address 2001:35af::23
- Secondary server residing at IPv4 address 1.1.24
- DNS refresh every day at 11:00pm

**WebUI**

Network > DNS > Host

**CLI**

```sh
set dns host dns1 2001:35af::23
set dns host dns2 1.1.1.24
set dns host schedule 23:00
save
```

**Requesting DNS and DNS Search List Information**

*Figure 13 on page 46 shows a DHCPv6 server and a DHCPv6 client. The DHCPv6 client receives information about the DNS devices from interface ethernet3 on the DHCPv6 server. This interface automatically transmits information about the primary, secondary, and tertiary DNS servers. The DHCPv6 client can then send DNS service requests to any of the DNS servers.*

**Figure 13: DNS Servers and DHCPv6 Client**

**WebUI (Server)**

Network > Interfaces > Edit (for ethernet3) > IPv6

Network > DHCPv6 > Edit (for ethernet3)

**WebUI (Client)**

Network > Interfaces > Edit (for ethernet3) > IPv6

Network > DHCPv6 > Edit (for ethernet3)

**CLI (Server)**

```sh
set interface ethernet3 ipv6 mode router
set interface ethernet3 ipv6 enable
set interface ethernet3 dhcp6 server
set interface ethernet3 dhcp6 server enable
set interface ethernet3 dhcp6 server options dns dns1 3af4:45ef::12
set interface ethernet3 dhcp6 server options dns dns2 3af4:45ef::22
```
set interface ethernet3 dhcp6 server options dns dns3 3af4:45ef::43
save

CLI (Client)

set interface ethernet2 ipv6 mode host
set interface ethernet2 ipv6 enable
set interface ethernet2 dhcp6 client
set interface ethernet2 dhcp6 client enable
set interface ethernet2 dhcp6 client options request dns
set interface ethernet2 dhcp6 client options request search-list
save

Setting Proxy DNS Address Splitting

ScreenOS supports proxy DNS address splitting, by which you direct selected domain name queries to specific DNS servers. Address splitting has two advantages:

- Reduces overhead. You can relieve DNS servers from processing irrelevant service requests.
- Protects traffic. You can perform IPsec tunneling on queries sent to DNS servers.

The DNS proxy selectively redirects the DNS queries to specific DNS servers, according to partial or complete domain names. This is useful when VPN tunnels or PPPoE virtual links provide multiple network connectivity, and it is necessary to direct some DNS queries to one network while directing other queries to another network.

Some advantages of a DNS proxy are as follows:

- Domain lookups are usually more efficient. For example, DNS queries meant for the corporate domain (such as marketing.acme.com) could go to the corporate DNS server exclusively, while all others go to the ISP DNS server, which reduces the load on the corporate server. In addition, this can prevent corporate domain information from leaking into the Internet.
- DNS proxy allows you to transmit selected DNS queries through a tunnel interface, which prevents malicious users from learning about internal network configuration. For example, DNS queries bound for the corporate server can pass through a tunnel interface and use security features such as authentication, encryption, and anti-replay.

In the following example, you create two proxy-DNS entries that selectively forward DNS queries to different servers. See Figure 14 on page 48.
Any DNS query with an FQDN containing the domain name acme.com goes out through tunnel interface tunnel.1 to the corporate DNS server at IPv6 address 3aff:7483::fe34. For example, if a host sends a DNS query to www.acme.com, the device automatically directs the query to this server. (For this example, assume that the server resolves the query to IPv6 address 2001.2efa::2.)

Any DNS query with an FQDN containing the domain name acme_engineering.com goes out through tunnel interface tunnel.1 to the DNS server at IPv6 address 3aff:7483::fe21. For example, if a host sends a DNS query to intranet.acme_eng.com, the device directs the query to this server. (For this example, assume that the server resolves the query to IPv6 address 2001.2efa::5.)

All other DNS queries (denoted by an asterisk) bypass the corporate servers and go out through interface ethernet3 to the DNS server at IPv4 address 1.1.1.23. For example, if the host and domain name is www.juniper.net, the device automatically bypasses the corporate servers and directs the query to this server, which resolves the query to IPv4 address 63.126.135.170.

**WebUI**

Network > DNS > Proxy

Network > DNS > Proxy > New

**CLI**

```
set dns proxy
set dns proxy enable
set dns server-select domain .acme.com outgoing-interface tunnel.1 primary-server 3aff:7483::fe34
set dns server-select domain .acme_eng.com outgoing-interface tunnel.1 primary-server 3aff:7483::fe21
set dns server-select domain * outgoing-interface ethernet3 primary-server 1.1.1.23
```
Configuring PPPoE

An IPv6-enabled interface can be a Point-to-Point Protocol over Ethernet (PPPoE) client, which allows members of an IPv6 Ethernet LAN to make individual PPP connections with their ISP. As with IPv4 implementations, the device encapsulates each outgoing IP packet within a PPP payload, then encapsulates the PPP payload inside a PPPoE payload. PPPoE allows devices to operate compatibly on digital subscriber lines (DSL), Ethernet Direct, and cable networks run by ISPs using PPPoE for their clients' Internet access.

You set PPPoE at the interface level and then enable the interface. The interface negotiates with an access concentrator for an Internet Protocol Control Protocol (IPCP) prefix, then an IPv6 Control Protocol (IPv6CP) prefix.

NOTE: PPPoE for IPv6 supports Netscreen Redundancy Protocol (NSRP). For more information about PPPoE in dual-stack IPv6 environments, refer to RFC 4241.

Setting up an interface for PPPoE (dual-stack mode) consists of the following steps:

1. Create a PPPoE instance with username and password.
2. Specify that the PPPoE instance obtains IPv4 and IPv6 prefixes from the PPPoE access concentrator (AC).
3. Configure the device for IPv6 host mode.

After you enable PPPoE for the interface, the interface negotiates with an AC for an IPCP prefix, then an IPv6CP prefix. Either or both of these attempts could be successful. If both are successful, the interface operates in dual-stack mode. Otherwise, it operates in single-stack mode.

In the following example, you configure interface ethernet3 for PPPoE with the following settings:

- You name the PPPoE instance NY_Office and bind it to ethernet3.
- You set the PPPoE username as Richard_B and the password as er5cmdj.
- You configure the PPPoE instance to obtain an IPv4 address first and then an IPv6 address.

Figure 15 on page 50 shows a PPPoE client and server exchange.
NOTE: The WebUI section lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

WebUI

1. PPPoE Instance
   Network > PPPoE > New

2. Client Interface
   Network > Interfaces > Edit (for ethernet3)
   Network > Interfaces > Edit (for ethernet3) > IPv6

CLI

1. PPPoE Instance
   set pppoe name NY_Office username richard_b password er5cmdj
   set pppoe name NY_Office ppp ipcp ipv6cp
   set pppoe name NY_Office interface ethernet3

2. Client Interface
   set interface ethernet3 zone untrust
   set interface ethernet3 ipv6 mode host
   set interface ethernet3 ipv6 enable

Setting Fragmentation

An IPv6 router running ScreenOS uses the Path MTU in combination with the MTU to determine fragmentation.

NOTE: For more information about Path MTU for IPv6, refer to RFC 1981.

An IPv6 interface initially determines the Path MTU to equal the MTU of the first hop in the path. If any packet sent on that path is too large to be forwarded by a router along the path, that router discards the packet and returns an Internet Control Message Protocol
version 6 (ICMPv6) Packet Too Big (PTB) message to the source router. Upon receipt of a PTB message, the source router reduces its Path MTU to match the MTU reported in the PTB message. This process might occur several times before the Path MTU discovery process ends because the packet might have to pass through other routers with smaller MTUs further along the path.

The device applies the Path MTU to traffic going through the device and to traffic originating in the device. For through traffic, if any fragmentation is required before forwarding a packet out of an interface at the flow level, the interface sends back an ICMPv6 PTB message with the MTU set to the outgoing interface’s MTU.

NOTE: For devices that do not allow you to configure Path MTU, the value is 1500.

For fragmentation to occur, you must enable Path MTU for the interface. For devices that accept a configured value, you can set a value from 1280 to 1500.

**WebUI**

Network > Interfaces > Edit

In the Maximum Transfer Unit (MTU) Admin MTU: Enter the MTU value, then click OK.

**CLI**

```
set interface trust trust-vr mtu 1280
save
```

NOTE: For advanced configuration examples for manual tunneling with fragmentation enabled, see “Manual Tunneling with Fragmentation Enabled” on page 119.
CHAPTER 4

Static and Dynamic Routing

ScreenOS supports static routing and dynamic routing with Routing Information Protocol next-generation (RIPng).

This chapter contains the following sections:

- Overview on page 53
- Static Routing on page 55
- RIPng Configuration on page 56
- Global RIPng Parameters on page 58
- RIPng Interface Parameters on page 62
- Viewing Routing and RIPng Information on page 66
- Configuration Examples on page 70

Overview

Dual-stack architecture allows the security device to receive, process, and forward IPv6 traffic and supports assignment of an IPv4 address, at least one IPv6 prefix, or both. This allows the device to exchange packets between dissimilar networks and supports security policies between remote networks over dissimilar WAN backbones.

The next sections explain IPv4/IPv6 routing tables, and static and dynamic routing concepts.

Dual Routing Tables

If you configure an interface to have both IPv4 and IPv6 addresses, the virtual router to which the interface is bound contains two separate routing tables: one for IPv4 entries and one for IPv6 entries. Both tables reside in the same virtual router.

For example, if you bind an interface to a zone bound to the trust-vr virtual router, and then you configure the interface for dual-stack mode, the trust-vr virtual router builds and maintains an IPv4 routing table and an IPv6 routing table.

Figure 16 on page 54 shows a security device with two Ethernet interfaces:

- Ethernet1 runs in dual-stack mode and maintains two routing tables.
- Ethernet3 runs in IPv4 mode only. The trust-vr for ethernet3 maintains only one routing table.

Figure 16: Dual-Stack Router Behavior

ScreenOS supports static routing and dynamic routing with Routing Information Protocol next-generation (RIPng), an Interior Gateway Protocol (IGP) that uses a distance-vector algorithm to determine the best route to a destination, using the hop count as the metric. RIPng supports route redistribution to import known routes, from a router running a different protocol, into the current RIPng routing instance. For example, you can import static routes from a virtual router into a RIPng instance. RIPng is intended only for use in IPv6 networks.

NOTE: For more information about RIPng, refer to RFCs 2080 and 2081.

Upstream and Downstream Prefix Delegation

In some network topologies, devices delegate prefixes to downstream devices, which can use the prefixes to autoconfigure other devices. For example, a corporate WAN might use multiple security devices used in the following ways:

- Customer Premises Equipment (CPE) routers to delegate IP addresses to local hosts
- Gateway routers to delegate subnetwork prefixes to the CPE routers
- Internet Service Provider (ISP) routers further upstream to delegate network prefixes to gateway routers
Static Routing

The process for configuring static routes for IPv6 interfaces is the same as for IPv4 interfaces. The difference is the address notation. For more information about IPv4 static routing, see Static Routing.

In the following example, you configure two interfaces.

- ethernet2 IPv4 address 1.1.2.1/24 (optional)
- ethernet2 configured in router mode with IPv6 address 32f1:250a::02/48
- ethernet2 bound to trust zone and enabled for route advertising to local hosts
- ethernet3 configured in router mode with IPv6 address 32f1:250a::03/48
- Two static routing entries:
  - 32f1:250a::01/48 for ethernet2, advertised to local hosts
  - ::/0 for ethernet3, external gateway 27a6::210:ea1:71ff:fe36

WebUI

1. Interfaces
   - Network > Interfaces > Edit (ethernet2)
   - Network > Interfaces > Edit (ethernet2) Static IP: (select)
   - Network > Interfaces > Edit (ethernet2) IPv6
   - Network > Interfaces > Edit (ethernet2) > IPv6
   - Network > Interfaces > Edit (ethernet2) > IPv6 > ND/RA Settings
   - Network > Interfaces > Edit (ethernet3)

2. Routes
   - Network > Routing > Routing Entries New (trust-vr)
   - Network > Routing > Routing Entries New (trust-vr) > Gateway: (select)

CLI

1. Interfaces
   
   set interface ethernet2 zone trust
   set interface ethernet2 ip 1.1.2.1/24
   set interface ethernet2 ipv6 mode router
   set interface ethernet2 ipv6 enable
   set interface ethernet2 ipv6 ip 32f1:250a::02/48
   set interface ethernet2 ipv6 ra transmit
   set interface ethernet2 ipv6 ra link-mtu
   set interface ethernet2 ipv6 ra link-address
   set interface ethernet3 zone untrust
   set interface ethernet2 ipv6 mode router
   set interface ethernet2 ipv6 enable
set interface ethernet3 ipv6 32f1:250a::03/48

2. Routes

set vrouter trust-vr route 32f1:250a::01/48 interface ethernet2
set vrouter trust-vr route ::/0 interface ethernet3 gateway 27a6::210:ea1:71ff:fe36

RIPng Configuration

You create RIPng on a per-virtual router basis on a security device. If you have multiple virtual routers (VRs) within a system, you can enable multiple instances of RIPng.

NOTE: Before you configure a dynamic routing protocol on a security device, you should assign a VR ID. For more information, see Fundamentals.

This section describes the following basic steps to configure RIPng on a security device:

1. Create the RIPng routing instance in a VR.
2. Enable the RIPng instance.
3. Enable RIPng on interfaces that connect to other RIPng routers.
4. Redistribute routes learned from different routing protocols (such as OSPF, BGP, or statically configured routes) into the RIPng instance.

This section describes how to perform each of these tasks using the CLI or the WebUI.

Optionally, you can configure RIPng parameters such as the following:

• Global parameters, such as timers and trusted RIPng neighbors, that are set at the VR level for RIPng (see “Global RIPng Parameters” on page 58)

• Interface parameters that are set on a per-interface basis for RIPng (see “RIPng Interface Parameters” on page 62)

Creating and Deleting a RIPng Instance

You create and enable a RIPng routing instance on a specific virtual router (VR) on a security device. When you create and enable a RIPng routing instance on a VR, RIPng transmits and receives packets on all RIPng-enabled interfaces in the VR.

Deleting a RIPng routing instance in a VR removes the corresponding RIPng configurations for all interfaces that are in the VR.

For more information about VRs and configuring a VR on security devices, see Routing.

Creating a RIPng Instance

You create a RIPng routing instance on the trust-vr and then enable RIPng.
**WebUI**

Network > Routing > Virtual Router (trust-vr) > Edit: Enter a Virtual Router ID, then select **Create RIPng Instance**.

Select Enable RIPng, then click **OK**.

**CLI**

1. **Router ID**
   
   ```
   set vrouter trust-vr router-id 10
   ```

2. **RIPng Routing Instance**
   
   ```
   set vrouter trust-vr protocol ripng
   set vrouter trust-vr protocol ripng enable
   save
   ```

**Deleting a RIPng Instance**

In this example, you disable the RIPng routing instance in the trust-vr. RIPng stops transmitting and processing packets on all RIPng-enabled interfaces of the trust-vr.

**WebUI**

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance: Deselect Enable RIPng and then click **OK**.

Network > Routing > Virtual Router (trust-vr) > Edit > Delete RIPng Instance and then click **OK** at the confirmation prompt.

**CLI**

```
unset vrouter trust-vr protocol ripng enable
unset vrouter trust-vr protocol ripng
save
```

**Enabling and Disabling RIPng on an Interface**

By default, RIPng is disabled on all interfaces in the virtual router (VR), and you must explicitly enable it on an interface. When you disable RIPng at the interface level, RIPng does not transmit or receive packets on the specified interface. Interface configuration parameters are preserved when you disable RIPng on an interface.

**NOTE:** If you disable the RIPng routing instance in the VR (see “Deleting a RIPng Instance” on page 57), RIPng stops transmitting and processing packets on all interfaces in the VR.

**Enabling RIPng on an Interface**

In this example, you enable RIPng on the Trust interface.
WebUI
Network > Interface > Edit (for Trust) > RIPng: Select Protocol RIPng Enable, then click Apply.

CLI
```
set interface trust protocol ripng enable
save
```

Disabling RIPng on an Interface
In this example, you disable RIPng on the Trust interface. The `unset interface interface_name protocol ripng` command unbinds the existing instance of RIPng from the interface. To disable RIP for the interface enter the `unset interface interface_name protocol ripng enable` command before saving.

WebUI
Network > Interface (for Trust) > RIPng: Clear Protocol RIPng Enable, then click Apply.

CLI
```
unset interface trust protocol ripng
unset interface trust protocol ripng enable
save
```

Global RIPng Parameters
This section describes RIPng global parameters that you can configure at the virtual router (VR) level. When you configure a RIPng parameter at the VR level, the parameter setting affects operations on all RIPng-enabled interfaces. You can modify global parameter settings through the RIPng routing protocol context in the CLI or by using the WebUI.

Table 4 on page 58 lists the RIPng global parameters and their default values.

Table 4: Global RIPng Parameters and Default Values

<table>
<thead>
<tr>
<th>RIPng Global Parameter</th>
<th>Description</th>
<th>Default Value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advertise default route</td>
<td>Specifies whether the default route (::/0) is advertised.</td>
<td>Disabled</td>
</tr>
<tr>
<td>Default metric</td>
<td>Default metric value for routes imported into RIPng from other protocols, such as OSPF and BGP.</td>
<td>10</td>
</tr>
<tr>
<td>Flush timer</td>
<td>Specifies, in seconds, when a route is removed from the time the route is invalidated.</td>
<td>120 seconds</td>
</tr>
<tr>
<td>Invalid timer</td>
<td>Specifies, in seconds, when a route becomes invalid from the time a neighbor stops advertising the route.</td>
<td>180 seconds</td>
</tr>
<tr>
<td>Maximum neighbors</td>
<td>The maximum number of RIPng neighbors allowed. To list the neighbors for a particular interface, enter the <code>get interface interface_name protocol ripng</code> command.</td>
<td>256</td>
</tr>
</tbody>
</table>
### Table 4: Global RIPng Parameters and Default Values  

<table>
<thead>
<tr>
<th>RIPng Global Parameter</th>
<th>Description</th>
<th>Default Value(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redistribute routes</td>
<td>Provides a way to route traffic coming from another dynamic routing protocol, such as Open Shortest Path First (OSPF), or static routes.</td>
<td>Disabled</td>
</tr>
<tr>
<td>Reject default routes</td>
<td>Specifies whether RIPng rejects a default route learned from another protocol. See “Rejecting Default Routes” on page 59.</td>
<td>Disabled</td>
</tr>
<tr>
<td>Incoming route map</td>
<td>Specifies the filter for routes to be learned by RIPng.</td>
<td>None</td>
</tr>
<tr>
<td>Outgoing route map</td>
<td>Specifies the filter for routes to be advertised by RIPng.</td>
<td>None</td>
</tr>
<tr>
<td>Update threshold</td>
<td>Specifies the number of updates the device processes before the update timer expires. If the threshold is set as 5 and if it receives 10 updates (not number of routes) before the update timer expires, the device drops the last 5 updates. After the update timer is reset another 5 updates are accepted and so on.</td>
<td>Zero (0) seconds</td>
</tr>
<tr>
<td>Trusted neighbors</td>
<td>Specifies an access list that defines RIPng neighbors. If no neighbors are specified, RIPng uses multicasting or broadcasting to detect neighbors on an interface. See “Configuring Trusted Neighbors” on page 60.</td>
<td>All neighbors are trusted</td>
</tr>
<tr>
<td>Update timer</td>
<td>Specifies, in seconds, when to issue updates of RIPng routes to neighbors.</td>
<td>30 seconds</td>
</tr>
</tbody>
</table>

### Advertising the Default Route

You can change the RIPng configuration to include the advertisement of the default route (a non-RIPng route) and change the metric associated with the default route present in a particular VR routing table.

By default, the default route (::/0) is not advertised to RIPng neighbors. The following command advertises the default route to RIPng neighbors in the trust-vr VR with a metric of 5 (you must enter a metric value). The default route must exist in the routing table.

**WebUI**

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance: Enter the following, then click OK:

- Advertising Default Route: (select)
- Metric: 5

**CLI**

```
set vrouter trust-vr protocol ripng adv-default-route metric number 5
save
```

### Rejecting Default Routes

In a Route Detour Attack, a router inserts a default route (::/0) into the routing domain in order to detour packets to itself. The router can then drop the packets, causing service disruption, or it can obtain sensitive information in the packets before forwarding them.
On Juniper Networks security devices, RIPng by default accepts any default routes that are learned in RIPng and adds the default route to the routing table.

In the following example, you configure the RIPng routing instance running in trust-vr to reject any default routes that are learned in RIPng.

**WebUI**

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance: Enter the following, then click **OK**:

Reject Default Route Learnt by RIPng: (select)

**CLI**

```
set vrouter trust-vr protocol ripng reject-default-route
save
```

### Configuring Trusted Neighbors

Multi-access environments can allow devices, including routers, to be connected into a network relatively easily. This can cause stability or performance issues if the connected device is not reliable. To prevent this problem, you can use an access list to filter the devices that are allowed to become RIPng neighbors. By default, RIPng neighbors are limited to devices that are on the same subnet as the virtual router (VR).

In this example, you configure the following global parameters for the RIPng routing instance running in the trust-vr:

- Maximum number of RIPng neighbors is 1.
- The IP address of the trusted neighbor, 2eee::5/64, is specified in an access-list.

**WebUI**

Network > Routing > Virtual Router (trust-vr) > Access List > New: Enter the following, then click **OK**:

Access List ID: 10
Sequence No.: 1
IP/Netmask: 2eee::5/64
Action: Permit (select)

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance: Enter the following, then click **OK**:

Trusted Neighbors: (select), 10
Maximum Neighbors: 1

**CLI**

```
set vrouter trust-vr
device(trust-vr)-> set access-list 10 permit ip 2eee::5/64 1
device(trust-vr)-> set protocol ripng
device(trust-vr/ripng)-> set max-neighbor-count 1
device(trust-vr/ripng)-> set trusted-neighbors 10
```
Redistributing Routes

Route redistribution is the exchange of route information between routing protocols. For example, you can redistribute the following types of routes into the RIPng routing instance in the same virtual router (VR):

- Routes learned from BGP
- Routes learned from OSPF
- Directly connected routes
- Imported routes
- Statically configured routes

You need to configure a route map to filter the routes that are redistributed. For more information about creating route maps for route redistribution, see Routing.

Routes imported into RIPng from other protocols have a default metric of 10. You can change the default metric (see “Global RIPng Parameters” on page 58).

In this example, you redistribute static routes that are in the subnetwork 2eee::/64 to RIPng neighbors in the trust-vr. To do this, you first create an access list to permit addresses in the 2eee::/64 subnetwork. Then, configure a route map that permits addresses that match the access list you configured. Use the route map to specify the redistribution of static routes into the RIPng routing instance.

WebUI

Network > Routing > Virtual Router (trust-vr) > Access List > New: Enter the following, then click OK:

- Access List ID: 20
- Sequence No.: 1
- IP/Netmask: 2eee::/64
- Action: Permit (select)

Network > Routing > Virtual Router (trust-vr) > Route Map > New: Enter the following, then click OK:

- Map Name: rtmap1
- Sequence No.: 1
- Action: Permit (select)
- Match Properties:
  - Access List: (select), 20 (select)

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance > Redistributable Rules: Enter the following, then click Add:

- Route Map: rtmap1 (select)
- Protocol: Static (select)
CLI

set vrouter trust-vr access-list 20 permit ip 2eee::/64 1
set vrouter trust-vr route-map name rtmap1 permit 1

Protecting Against Flooding by Setting an Update Threshold

A malfunctioning or compromised router can flood its neighbors with RIPng routing update packets. On virtual router (VRs), you can configure the maximum number of update packets that can be received on a RIPng interface within an update interval to avoid flooding of update packets. All update packets that exceed the configured update threshold are dropped. If you do not set an update threshold, all update packets are accepted.

In networks where neighbors have large routing tables, specifying an update threshold can impair the security device's ability to learn valid routes. Large routing tables accept and generate a large number of routing updates including flash updates within a given period. Update packets to the security device that exceed the changed threshold will be dropped and important routes might not be learned.

In this example, you set the maximum number of routing update packets that RIPng can receive on an interface to 4.

WebUI

Network > Routing > Virtual Router (trust-vr) > Edit > Edit RIPng Instance: Enter the following, then click OK:

Maximum Number Packets per Update Time: (select), 4

CLI

set vrouter trust-vr protocol ripng threshold-update 4
save

RIPng Interface Parameters

This section describes RIPng parameters that you configure at the interface level. When you configure a RIPng parameter at the interface level, the parameter setting affects the RIPng operation only on the specific interface. You can modify interface parameter settings with interface commands in the CLI or by using the WebUI.

Table 5 on page 62 lists the RIPng interface parameters and their default values.

<table>
<thead>
<tr>
<th>RIPng Interface Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RIPng metric</td>
<td>Specifies the RIPng metric for the interface.</td>
<td>1</td>
</tr>
</tbody>
</table>
Table 5: RIPng Interface Parameters and Default Values (continued)

<table>
<thead>
<tr>
<th>RIPng Interface Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Passive mode</td>
<td>Specifies that the interface is to receive but not transmit RIPng packets.</td>
<td>No</td>
</tr>
<tr>
<td>Incoming route map</td>
<td>Specifies the filter for routes to be learned by RIPng.</td>
<td>None.</td>
</tr>
<tr>
<td>Outgoing route map</td>
<td>Specifies the filter for routes to be advertised by RIPng.</td>
<td>None.</td>
</tr>
<tr>
<td>Split-horizon</td>
<td>Specifies whether to enable split-horizon (do not advertise routes learned from an interface in updates sent to the same interface). If split horizon is enabled with the poison-reverse option, routes that are learned from an interface are advertised with a metric of 16 in updates sent to the same interface.</td>
<td>Split-horizon is enabled. Poison reverse is disabled.</td>
</tr>
</tbody>
</table>

Route, Interface, and Offset Metrics

A RIPng uses a positive integer to indicate the number of hops needed to reach a router. A device uses three values to calculate this number:

- The route metric is an integer associated with a particular route prefix.
- The interface cost metric is an integer associated with a particular interface configured for RIPng operation.
- The offset metric is a value added to the total.

The method by which the device derives the total metric depends on the interface through which the traffic flows.

- If the interface receives incoming traffic, the total metric is:
  route metric + interface cost metric + offset metric
- If the interface transmits outgoing traffic, the interface cost metric does not apply, so the total metric is:
  route metric + offset metric

Access Lists and Route Maps

In this example, you set up an IPv6 access list for the trust-vr with an access control list (ACL) ID of 10 and create a route map with prefix ::/0.

**NOTE:** To create an IPv4 access list and route map, see Configuring a Route Map.

WebUI

Network > Routing > Virtual Routers > Access Lists > New (trust-vr)
Network > Routing > Virtual Routers > Route Maps (trust-vr) > New
**CLI**

```
set vrouter trust-vr
set access-list ipv6 10
set access-list 10 permit ip ::/0 10
set route-map ipv6 name rm_six permit 10
set match ip 10
end
```

**Static Route Redistribution**

In the following example, you configure two devices for RIPng, Device A and Device B. For Device B, you add 2 to the metric value received by a route map (default is 1).

You configure the devices as follows:

- **Device A** to transmit outgoing traffic to Device B with these metrics:
  - Route metric (5) +
  - Offset metric (1 by default)

  The total RIPng metric for outgoing packets is 6.

- **Device B** receives traffic from Device A with these metrics:
  - Route metric (4) +
  - Interface cost metric (7) +
  - Offset metric (2)

  The total RIPng metric for incoming packets is 13.

**WebUI (Device A)**

1. **IPv6 Interface**
   - Network > Interfaces > Edit (for ethernet3)
   - Network > Interfaces > Edit (for ethernet2) > IPv6
   - Network > Interfaces > Edit (for ethernet2) > IPv6 > ND/RA Settings
   - Network > Interfaces > Edit (for ethernet2) > RIPng

2. **RIPng Virtual Routing**
   - Network > Routing > Virtual Routers > Edit (for trust-vr) > Create RIPng Instance

3. **RIPng Interface Metric**
   - Network > Interfaces > Edit (for ethernet2) > IPv6

**CLI (Device A)**

1. **IPv6 Interface**
   - set interface ethernet3 zone trust
   - set interface ethernet3 ipv6 mode router
   - set interface ethernet3 ipv6 enable
set interface ethernet3 ipv6 ip 2eee::1/64
set interface ethernet3 ipv6 interface-id 1111111111111111
set interface ethernet3 ipv6 ra transmit
set interface ethernet3 protocol ripng enable

2. **RIPng Virtual Routing**
   - set vrouter trust-vr protocol ripng
   - set vrouter trust-vr protocol ripng enable
   - set vrouter trust-vr protocol ripng advertise-def-route always metric 5

3. **RIPng Interface Metric**
   - set interface ethernet3 protocol ripng metric 1

**WebUI (Device B)**

1. **IPv6 Interface**
   - Network > Interfaces > Edit (for Trust)
   - Network > Interfaces > Edit (for Trust) > IPv6
   - Network > Interfaces > Edit (for Trust) > IPv6 > ND/RA Settings

2. **Static Routes**
   - Network > Routing > Routing Entries

3. **RIPng Virtual Router**
   - Network > Routing > Virtual Routers > Edit (for trust-vr) > Create RIPng Instance
   - Network > Interfaces > Edit (for Trust) > RIPng
   - Network > Routing > Virtual Routers > Access List > New (for trust-vr)

4. **IPv6 Route-Map**
   - Network > Routing > Virtual Routers > Route Map > New (for trust-vr)
   - Network > Routing > Virtual Router > Edit (for trust-vr) > Create RIPng Instance

5. **Static Route Redistribution**
   - Network > Routing > Virtual Router > Edit (for trust-vr) > Edit RIPng Instance > Redistributable Rules

**CLI (Device B)**

1. **IPv6 Interface**
   - set interface trust zone trust
   - set interface trust ipv6 mode host
   - set interface trust ipv6 enable
   - set interface trust ipv6 interface-id 2222222222222222
   - set interface trust ipv6 ra accept

2. **Static Routes**
   - set route 3a51:94ef::1/48 interface trust metric 2 tag 23
   - set route 3a51:ee45::1/48 interface trust metric 3 tag 37
3. **RIPng Virtual Router**
   
   ```
   set vrouter trust-vr protocol ripng
   set vrouter trust-vr protocol ripng enable
   set interface trust protocol ripng enable
   set interface trust protocol ripng metric 7
   set vrouter trust-vr access-list ipv6 10
   set vrouter trust-vr access-list ipv6 10 permit ip 3a51::1/16 10
   ```

4. **IPv6 Route-Map**
   
   ```
   set vrouter trust-vr route-map ipv6 name abc permit 25
   set vrouter trust-vr route-map abc 25 match ip 10
   set vrouter trust-vr route-map abc 25 metric 4
   set vrouter trust-vr route-map abc 25 offset-metric 2
   set vrouter trust-vr protocol ripng route-map abc out
   set interface trust protocol ripng route-map abc out
   ```

5. **Static Route Redistribution**
   
   ```
   set vrouter trust-vr protocol ripng redistribute route-map abc protocol static
   save
   ```

### Configuring Split Horizon with Poison Reverse

In the following example, you configure split horizon with poison reverse for the interface.

**WebUI**

Network > Interfaces > Edit (for Trust) > RIPng: Enter the following, then click **OK**:

- Split Horizon: Enabled with poison reverse (select)

**CLI**

```
set interface trust protocol ripng split-horizon poison-reverse
save
```

### Viewing Routing and RIPng Information

After modifying RIPng parameters, you can view the following types of RIPng details:

- Database, which shows routing information
- Protocol, which gives RIPng and interface details for a virtual router (VR)
- Neighbor

### Viewing the Routing Table

You can view route information from the CLI.

**WebUI**

---

**NOTE:** You must use the CLI to view the complete routing table.
CLI

get route v6

Sample output:

untrust-vr (0 entries)

trust-vr (6 entries)

<table>
<thead>
<tr>
<th>ID</th>
<th>IP-Prefix</th>
<th>Interface</th>
<th>Gateway</th>
<th>P Pref</th>

</tbody>
</table>

Viewing the RIPng Database

You can verify RIPng routing information from the CLI. You can choose to view a complete list of all RIPng database entries or a single entry.

In this example, you view detailed information from the RIPng database. You can choose to view all database entries or limit the output to a single database entry by appending the IP address and mask of the desired VR.

In this example, you specify the trust-vr and append the prefix and IP address 10.10.10.0/24 to view only a single table entry.

WebUI

NOTE: You must use the CLI to view the RIPng database.

 CLI

get vrouter trust-vr protocol ripng database prefix 10.10.10.0/24

After you enter the following CLI command, you can view the RIPng database entry:

device->get vrouter trust-vr protocol ripng database 10.10.10.0/24

The RIPng database contains the following fields:

- **DBID**, the database identifier for the entry
- **Prefix**, the IP address and prefix
- **Nexthop**, the address of the next-hop (router)
- **If**, the type of connection (Ethernet or tunnel)
- **Cost metric** assigned to indicate the distance from the source
Flags can be one or more of the following: multipath (M), RIPng (R), Redistributed (I), Advertised default (D), Permanent (P), Summary (S), Unreachable (U), or Hold (H).

In this example, the database identifier is 7, the IP address and prefix is 2eee::/64, and the next hop is 2eee::100/64. It is an Ethernet connection with a cost of 2. The flags are M and R and indicate that this route is multipath and uses RIPng.

**Viewing RIPng Details by Virtual Router**

You can view complete RIPng information for a virtual router to check a configuration or verify that saved changes are active. You can limit output to only the interface summary table by appending interface to the CLI command.

**WebUI**

NOTE: You must use the CLI to view the RIPng details.

**CLI**

```
get vrouter trust-vr protocol ripng
```

Sample output:

```
device-> get vrouter trust-vr protocol ripng
get vrouter trust-vr protocol ripng
VR: trust-vr
----------------------------------
State: enabled
Version: 1
Default metric for routes redistributed into RIPng: 10
Maximum neighbors per interface: 256
Next RIPng update scheduled after: 7 sec
Advertising default route: disabled
Default routes learnt by RIPng will be accepted
Incoming routes filter and offset-metric: not configured
Outgoing routes filter and offset-metric: not configured
Update packet threshold is not configured
Total number of RIPng interfaces created on vr(trust-vr): 1

Update Invalid Flush (Timers in seconds)
-------------------------------------------
30     180   120

Flags: Split Horizon - S, Split Horizon with Poison Reverse - P, Passive - I

<table>
<thead>
<tr>
<th>Interface</th>
<th>IP-Prefix</th>
<th>Admin</th>
<th>State</th>
<th>Flags</th>
<th>NbrCnt</th>
<th>Metric</th>
<th>Ver-Rx/Tx</th>
</tr>
</thead>
<tbody>
<tr>
<td>ethernet3/4</td>
<td>fe80::210:dbff:fe8d</td>
<td>enabled</td>
<td>enabled</td>
<td>S</td>
<td>1</td>
<td>1</td>
<td>1/1</td>
</tr>
</tbody>
</table>
```

You can view RIPng settings, packet details, RIPng timer information, and a summarized interface table.

**Viewing RIPng Details by Interface**

You can view complete RIPng information for a specific interface to check a configuration or verify that saved changes are active.
NOTE: You must use the CLI to view the RIPng details.

CLI

```
get interface ethernet3/4 protocol ripng
```

Sample output:

```
VR: trust-vr
----------------------------------
Interface: ethernet3/4, IP: fe80::210:dbff:fe8d:3ea0/64, RIPng: enabled, Router: enabled
Receive version 1, Send Version 1
State: Up, Passive: No
Metric: 1, Split Horizon: enabled, Poison Reverse: disabled
Incoming routes filter and offset-metric: not configured
Outgoing routes filter and offset-metric: not configured
Current neighbor count: 1
Next update after: 16 sec
Transmit Updates: 30 (3 triggered), Receive Updates: 68
Update packets dropped because flooding: 0
Bad packets: 0, Bad routes: 0
Neighbors on interface ethernet3/4
```

<table>
<thead>
<tr>
<th>IpAddress</th>

<td>00:02:39</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Viewing RIPng Neighbor Information

You can view details about RIPng neighbors for a virtual router (VR). You can retrieve a list of information about all neighbors or an entry for a specific neighbor by appending the IP address of the desired neighbor. You can check the status of a route and verify the connection between the neighbor and the security device from these statistics.

In the following example you view RIPng neighbor information for the trust-vr.

WebUI

NOTE: You must use the CLI to view RIPng neighbor information.

CLI

```
get vrouter trust-vr protocol ripng neighbors
```

This command produces output similar to the following output:

```
n2-> get vr trust protocol ripng neighbors
VR: trust-vr
----------------------------------
Neighbors on interface trust
```

Copyright © 2012, Juniper Networks, Inc.
In addition to viewing the IP address, you can view the following RIPng neighbor information:

- Age of the entry
- Expiration time
- Number of bad packets
- Number of bad routes
- Flags: static (S), demand circuit (T), NHTB (N), down (D), up (U), poll (P), or demand circuit init (I)

### Configuration Examples

This section contains examples for using RIPng and static routing with tunnels with multiple security devices that behave as IPv6 hosts or IPv6 routers placed upstream or downstream from other devices.

#### Enabling RIPng on Tunnel Interfaces

The following example creates and enables a RIPng routing instance in trust-vr, on the Device-A device. You enable RIPng on both the VPN tunnel interface and the Trust zone interface. Only routes that are in the subnet 2eee::/64 are advertised to the RIPng neighbor on Device-B. This is done by first configuring an access list that permits only addresses in the subnet 2eee::/64, then specifying a route map abcd that permits routes that match the access list. You then specify the route map to filter the routes that are advertised to RIPng neighbors.

Figure 17 on page 70 shows the described network scenario.

#### Figure 17: Tunnel Interface with RIPng Example

WebUI (Device A)

Network > Routing > Virtual Router > Edit (for trust-vr) > Create RIPng Instance: Select Enable RIPng, then click OK.

Network > Routing > Virtual Router > Access List (for trust-vr) > New: Enter the following, then click OK:
Access List ID: 10
Sequence No.: 10
IP/Netmask: 2eee::/64
Action: Permit

Network > Routing > Virtual Router > Route Map (for trust-vr) > New: Enter the following, then click OK:

Map Name: abcd
Sequence No.: 10
Action: Permit
Match Properties:
Access List: (select), 10

Network > Routing > Virtual Router > Edit (for trust-vr) > Edit RIPng Instance: Select the following, then click OK:

Outgoing Route Map Filter: abcd

Network > Interfaces > Edit (for tunnel.1) > RIPng: Enter the following, then click Apply:

Enable RIPng: (select)

Network > Interfaces > Edit (for trust) > RIPng: Enter the following, then click Apply:

Enable RIPng: (select)

CLI (Device A)

`set vrouter trust-vr protocol ripng`  
`set vrouter trust-vr protocol ripng enable`  
`set interface tunnel.1 protocol ripng enable`  
`set interface trust protocol ripng enable`  
`set vrouter trust-vr access-list 10 permit ipv6 2eee::/64 10`  
`set vrouter trust-vr route-map ipv6 name abcd permit 10`  
`set vrouter trust-vr route-map ipv6 abcd 10 match ip 10`  
`set vrouter trust-vr protocol ripng route-map abcd out`  
`save`

Avoiding Traffic Loops to an ISP Router

Figure 18 on page 72 shows multiple devices configured to avoid traffic loop to the upstream ISP router. The ISP and gateway routers are in IPv6 router mode. The three customer premises equipment (CPE) devices are IPv6 hosts and receive delegated IPv6 prefixes from the ISP router through the gateway router. The RADIUS server resides in the Trust zone of the Gateway device.

In this example, you enable the route-deny feature on the interface of a gateway connected to the ISP router. This feature prevents the default route on the gateway from creating a traffic loop to the ISP router.
Configuring the Customer Premises Equipment

This section lists the configuration steps for setting up the CPE 1, CPE 2, and CPE 3. The CPE devices are IPv6 hosts. The IPv6 addresses are placeholders for the values that each device could autoconfigure.

1. Configure IPv6 interfaces for all CPE devices. When configuring a CPE device interface in IPv6 host mode, you do not have to explicitly assign the IPv6 prefix. The device accepts the prefix from the gateway router. For each CPE device configuration, we show and recommend assigning each IPv6 interface an interface ID.

2. Configure the following tunnels:
   a. CPE 1 with interface tunnel.1.
   b. CPE 2 with interface tunnel.2.
   c. CPE 3 with interface tunnel.3.

3. Define a VPN for each CPE.

4. Define an XAuth client user with username and password for hosts.

5. Configure the Gateway router.

NOTE: In your network, if one or more CPE devices do not specify an IPv6 prefix and use one or more IPv4 addresses, then you need to assign an IPv4 address to the gateway router interface.

6. Configure the ISP router.

NOTE: The WebUI section lists the navigational paths to the device configuration pages for CPE 1, CPE 2, and CPE 3. For specific values, see the specific CPE CLI sections that follow it.

**Configuring the Gateway**

This section lists the configuration steps for setting up the gateway router, an IPv6 router.

1. Configure the ethernet1 interface of gateway with the route-deny feature.

2. Configure the gateway with three tunnels (tunnel.1, tunnel.2, and tunnel.3).

3. Configure the XAuth server with users for the three IKE gateways (from CPE 1, CPE 2, and CPE 3). Specify RADIUS shared secret (juniper) and port number (1812).
4. Define static routes between the RADIUS server and gateway and define a default route from the gateway to the ISP router.

5. Define an IP pool (P1) with an IP range from 2fba::5555 to 2fba::8888 on the gateway (Device 2).

Configuring the ISP Router

This section lists the configuration steps for setting up the ISP router, an IPv6 router.

1. Configure the ISP router to reach the gateway router and the RADIUS server.
2. Configure accounts for the RADIUS server.
3. Define a static route on the ISP router to reach the 100.100.100.0/24 network. Make the next hop the ethernet1 interface IP address of the gateway.

WebUI (ISP Router)

1. Interfaces
   Network > Interfaces > Edit (for trust)
   Network > Interfaces > Edit (for trust) > IPv6
   Network > Interfaces > Edit (for untrust)
   Network > Interfaces > Edit (for untrust) > IPv6

2. Route
   Network > Routing > Routing Table > New (trust-vr)

CLI (ISP Router)

1. Interfaces
   set interface ethernet1 zone trust
   set interface ethernet1 ipv6 mode router
   set interface ethernet1 ipv6 enable
   set interface ethernet1 ipv6 interface-id 1111111111111111
   set interface ethernet1 ipv6 ip 3002::0001/64
   set interface ethernet1 ipv6 ra transmit
   set interface ethernet1 manage
   set interface ethernet1 route
   set interface ethernet2 zone trust
   set interface ethernet2 ipv6 mode router
set interface ethernet2 ipv6 enable
set interface ethernet2 ipv6 interface-id 2222222222222222
set interface ethernet2 ipv6 ip 3002::0002/64
set interface ethernet2 ipv6 ra transmit
set interface ethernet2 manage
set interface ethernet2 route

2. **Route**

   set vrouter trust-vr route 2fba::5555/64 interface ethernet1 gateway 3001::0004/64

**Setting a Null Interface Redistribution to OSPF**

In this example, you set a static route to a null interface and redistribute the routes to
the ISP router using Open Shortest Path First (OSPF) routing protocol. Any traffic sent
to this route is subject to redistribution to OSPF and becomes available to outside OSPF
devices.

1. Configure CPE 1, CPE 2, and CPE 3 as described in “Configuring the Customer Premises
   Equipment” on page 72.

2. Configure the gateway router as described in “Configuring the Gateway” on page 75.

3. Configure the ISP router as described in “Configuring the ISP Router” on page 78.

**WebUI (OSPF for Gateway Router)**

Network > Routing > Virtual Router > Edit

**CLI (Gateway)**

set vrouter trust-vr route 2fba::5555/64 interface null
set vrouter trust-vr
set protocol ospf
set area 0
set enable
set interface ethernet1 protocol ospf area 0
set interface ethernet1 protocol ospf enable
set vrouter trust-vr
set route-map name abc permit 10
set match ip 10
set access-list 10 permit ip 2fba::5555/64 10
set vrouter trust-vr protocol ospf redistribute route-map abc protocol static

**WebUI (ISP)**

Network > Routing > Virtual Router > Edit

**CLI (ISP)**

set vrouter trust-vr
set protocol ospf
set area 0
set enable
set interface ethernet1 protocol ospf area 0
set interface ethernet1 protocol ospf enable
Redistributing Discovered Routes to OSPF

You can configure the gateway router to redistribute discovered routes to Open Shortest Path First (OSPF) routing protocol. To do this, append the following command information to the configuration that appears on “Avoiding Traffic Loops to an ISP Router” on page 71.

**WebUI (Gateway)**

Network > Routing > Virtual Router > Edit

**CLI (Gateway)**

```
set vrouter trust-vr protocol ospf redistribute route-map abc protocol discovered
```

Setting Up OSPF-Summary Import

In this example, you set up the gateway and ISP routers to redistribute discovered routes to OSPF routing protocol. See “Avoiding Traffic Loops to an ISP Router” on page 71 for the full configuration and illustration.

1. Configure CPE 1, CPE 2, and CPE 3 as described in “Configuring the Customer Premises Equipment” on page 72 and the ISP router as described in “Configuring the ISP Router” on page 78.

2. Configure the gateway as described in “Configuring the Gateway” on page 75 and then redistribute the static routes to the ISP router. Append the added configuration below.

3. Configure the import summary feature for OSPF.

**WebUI (Gateway)**

Network > Routing > Routing Table > New (trust-vr)

Network > Routing > Virtual Router > Edit

**CLI (Gateway)**

1. **OSPF**

   ```
   set vrouter trust-vr
   set protocol ospf
   set area 0
   set enable
   set interface ethernet1 protocol ospf area 0
   set interface ethernet1 protocol ospf enable
   set vrouter trust-vr
   set route-map name abc permit 10
   set match ip 10
   exit
   set access-list 10 permit ip 2fba::5555/64 10
   set vrouter trust-vr protocol ospf redistribute route-map abc protocol discovered
   set vrouter trust-vr protocol ospf summary-import 2fba::5555/64
   ```
CHAPTER 5

Address Translation

When two hosts using different IP stacks exchange service requests through a security device, the device must perform address translation for all packets before it can transmit them across an IPv4/IPv6 boundary. This chapter describes the translation process. It contains the following sections:

• Overview on page 81
• Configuration Examples on page 84

Overview

Network Address Translation with Port Translation (NAT-PT) is a mechanism that performs address translation for packets transmitted between hosts that use incompatible IP stacks. For example, a packet generated by an IPv6 host, transmitted over an IPv4-only backbone to an IPv4 host, must have IPv4 source and destination addresses. NAT-PT provides such addresses by translating the original IPv6 source and destination addresses to IPv4.

Devices perform address translations using the following mechanisms.

• Dynamic IP (DIP), which generates new source addresses from a defined address pool.
• Mapped IP (MIP), which translates destination addresses by performing direct mapping between one address and another. MIP can also map addresses to specified subnets.

Figure 19 on page 81 shows how a device might use NAT-PT to transmit an IPv6 service request packet to an IPv4 host.

Figure 19: Network Address Translation (NAT) Across an IPv4/IPv6 Boundary
1. The IPv6 host transmits an IPv6 service request packet to the local IPv6 interface of a security device.

2. The security device translates the packet addresses to IPv4. It uses DIP to translate the source address and uses MIP to translate the destination address.

3. The destination host receives and processes the IPv4 packet.

NAT-PT converts IPv6 packets into IPv4 packets or IPv4 packets into IPv6 packets, which makes them routable across the IPv6/IPv4 boundary.

When an IPv4 host translates addresses between IPv4 and IPv6, it uses a MIP to generate an IPv4-\emph{mapped} destination address. An IPv4-\emph{mapped} address is a global unicast IPv6 address that contains an embedded IPv4 address. IPv4-\emph{mapped} addresses are in the format IPv6::$a.b.c.d$, where:

* IPv6 is the IPv6 subnet portion of the destination address.
* $a.b.c.d$ is the embedded IPv4 address (expressed in decimal notation).

**Translating Source IP Addresses**

When two hosts that use dissimilar IP stacks exchange packets through a device, the device must translate the source address of each packet to an address compatible with the destination host. For example, an IPv6 packet transmitted into an IPv4 network needs an IPv4 source address; otherwise, the packet cannot successfully traverse the IPv4/IPv6 boundary. To translate source addresses, devices can use dynamic IP (DIP), a mechanism that automatically generates source IP addresses from a defined pool of addresses.

**DIP from IPv6 to IPv4**

Figure 20 on page 82 shows an IPv6 host sending a request packet to an IPv4 server over an IPv4 backbone. The security device, an IPv6 router, replaces the IPv6 source address in the packet header with an IPv4 address.

In this example, the device takes IPv4 source addresses 1.1.1.2 from the DIP pool and uses it to replace the original IPv6 source address (27a6::210:ea1:71ff:fe36). It then transmits the packet across the IPv6/IPv4 boundary.
**DIP from IPv4 to IPv6**

Figure 21 on page 83 shows an IPv4 host sending a request packet to an IPv6 server in zone B over an IPv6 backbone. The security device replaces the IPv4 source address in the packet header with an IPv6 address.

---

**Figure 21: DIP from IPv4 to IPv6**

In this example, the device generates IPv6 source addresses 27f2::42ff:fe02 from the DIP pool and uses it to replace the original IPv4 source address (10.1.1.15). It then sends the packet across the IPv4/IPv6 boundary.

---

**Translating Destination IP Addresses**

When two hosts that use dissimilar IP stacks exchange packets through a device, the device must translate the destination address of each packet to an address compatible with the destination host. For example, an IPv6 packet transmitted into an IPv4 network needs an IPv4 destination address; otherwise, the packet cannot cross the IPv4/IPv6 boundary. To perform this translation, devices use mapped IP (MIP).

---

**MIP from IPv6 to IPv4**

Figure 22 on page 83 shows an IPv6 host sending a request packet to an IPv4 server over an IPv4 backbone, the device must use a destination address that matches the IP address format of the destination host.

---

**Figure 22: MIP from IPv6 to IPv4**

1. An IPv6 Host generates an IPv6 service request packet and sends it to the security device. The packet enters Zone A.

2. The device replaces the destination address with the MIP address and sends the packet to Zone B.
3. The destination device receives the packet somewhere in Zone B. To this device, the packet is an IPv4 packet.

In this example, the IPv6 host addresses the packet to the MIP address (27a6::210:ea1:71ff:fe15). The device translates this MIP to the address of the remote IPv4 host (10.2.2.15).

**MIP from IPv4 to IPv6**

Figure 23 on page 84 shows an IPv4 host sending a request packet to an IPv6 server over an IPv6 backbone. The security device uses a destination address that matches the IP address format of the destination host.

**Figure 23: MIP from IPv4 to IPv6**

1. An IPv4 Host generates an IPv4 service request packet and sends it to the security device. The packet enters Zone A.
2. The security device replaces the destination address with the MIP address and sends the packet to Zone B.
3. The destination device receives the packet somewhere in Zone B. To this device, the packet is an IPv6 packet.

In this example, the IPv4 host addresses the packet to the MIP address (10.1.1.25). The device translates this MIP to the address of the remote IPv6 host (322f::49a:3af:4ff:fe25).

A MIP can also map to IPv6 networks and subnets.

**Configuration Examples**

The following sections contain examples of NAT-PT scenarios and translation with domain name services.

When a device transmits a service request packet from a host and forwards it to another host that uses a different IP stack, the device can use a NAT-PT policy to translate the IPv6 source and destination addresses of the outgoing packet. For example, a device residing at the border between an IPv6 network and an IPv4 WAN might transmit an outgoing IPv6 service request sent by an IPv6 host, using a NAT-PT policy to translate the source and destination addresses to IPv4.

**IPv6 Hosts to Multiple IPv4 Hosts**

When you need to send service requests from IPv6 hosts to multiple IPv4 destination hosts, define a policy that uses **IPv6-to-IPv4 network mapping** to translate the destination address.
Figure 24 on page 85 shows the NAT-PT mechanism mapping local IPv6 addresses to IPv4 addresses in a remote IPv4 network. When a local IPv6 host transmits an outgoing service request packet through the device, the device uses MIP to generate an IPv6 destination address that uses IPv4-mapped format. When the device transmits packets across the IPv4/IPv6 boundary, it translates these destination addresses into IPv4 addresses.

IPv6 hosts can send HTTP requests through a device across an IPv6/IPv4 boundary. To send such a request, the user enters an IPv4-mapped address (such as 27a6::10.1.1.15) in the URL field of the browser. Such an entry might look like http://[27ab::10.1.1.15]. The device automatically translates this address into its hexadecimal equivalent. To IPv6 hosts the destinations appear to be IPv6-compatible devices. However, before transmitting the HTTP request packet over the boundary, the device translates the address to its IPv4 equivalent, which allows the packet to traverse the IPv4 WAN. To the target IPv4 servers, the packets are completely IPv4-compatible.

In the following example, you configure a device to allow hosts in an island IPv6 network to send HTTP service requests to hosts in a remote IPv4 network. Because the destination address is a network instead of a single host, the device uses IPv4-mapped addresses to represent individual remote nodes.

Host A generates an IPv6 service request packet and addresses it to Host B. It specifies an IPv6 destination address in the MIP table. The packet then goes from Zone A to Zone B.

Device A gets a source address from the DIP pool and translates the MIP address to the IPv4 address of the destination host. It then sends the packet out the interface to Device B.

The device translates the IPv4-mapped address to its IPv4 equivalent and then assigns it to the destination address of the outgoing packet.

IPv6 Hosts to a Single IPv4 Host

When you need to send service requests from IPv6 hosts to a single IPv4 host, you can define a policy that uses IPv6-to-IPv4 host mapping to translate the destination address.
This NAT-PT mechanism maps an IPv6 address to the IPv4 address of a single remote IPv4 host. When a local IPv6 host transmits an outgoing service request packet through the device, the device uses the mapped address for the IPv4 destination address in the packet header. This translation allows the outgoing packet to traverse the IPv6/IPv4 boundary and establish communication with the remote host.

Figure 25 on page 87 shows IPv6 hosts sending HTTP requests to a single IPv4 server through a device across an IPv6/IPv4 boundary.

Figure 25: IPv6-to-IPv4 Host Mapping

To send a request, the user enters an IPv6 address (such as 27a6::15) in the URL field of a browser. To IPv6 hosts the destination appears to be an IPv6-compatible device. However, before transmitting the HTTP request packet over the IPv6/IPv4 boundary, the device translates the address to its mapped IPv4 address, which allows the packet to traverse the IPv4 WAN. To the target IPv4 server, the packet is completely IPv4-compatible.

In the following example, you configure a device to allow hosts in an island IPv6 network to send HTTP requests to a single remote IPv4 host (10.2.2.15).

   ```

**IPv4 Hosts to Multiple IPv6 Hosts**

When you need to send service requests from local IPv4 hosts to multiple remote IPv6 hosts, you can define a policy that uses *IPv4-to-IPv6 network mapping*.

Figure 26 on page 88 shows NAT-PT mapping a local IPv4 address to an IPv6 network (or subnet). When a local IPv4 host transmits an outgoing IPv4 service request packet through the device, the device translates the mapped address to the IPv6 address and assigns it to the destination address of the packet header. This translation allows the outgoing packet to traverse the IPv4/IPv6 boundary to establish communication with the remote IPv6 host.

Figure 26: IPv4-to-IPv6 Network Mapping
The mapped IPv4 address indirectly represents the remote IPv6 host. In effect, the local IPv4 hosts can view the remote host as part of the local IPv4 network.

Because the MIP belongs to the same subnet as the local IPv4 hosts, the hosts can view the remote host as part of the local IPv4 network.

IPv4 Hosts to a Single IPv6 Host

When you need to send service requests from local IPv4 hosts to a single remote IPv6 host, define a policy that uses IPv4-to-IPv6 host mapping.

Figure 27 on page 90 shows an IPv4 host transmitting an outgoing IPv4 service request packet through the device. The device translates the mapped address to an IPv6 address, and assigns it to the destination address of the packet header. This translation allows the outgoing packet to traverse the IPv4/IPv6 boundary to establish communication with the remote IPv6 host.

Figure 27: IPv4-to-IPv6 Host Mapping

The MIP belongs to the same subnet as the local IPv4 hosts, so hosts view the remote host as part of the local IPv4 network.

**Translating Addresses for Domain Name System Servers**

Domain Name System (DNS) allows network devices to identify each other using domain names instead of IP addresses. An external DNS server keeps a table of domain names, each name having at least one associated IP address. You can use these domain names (as well as IP addresses) for identifying endpoints in policy definitions.

Some domain names can have both IPv4 and IPv6 addresses. For example, the hypothetical domain names acme.com and juniper.net could have the following addresses:

<table>
<thead>
<tr>
<th>Domain Name</th>
<th>IPv4 Addresses</th>
<th>IPv6 Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.acme.com">www.acme.com</a></td>
<td>1.2.2.15</td>
<td>27a6::e02:20f</td>
</tr>
<tr>
<td></td>
<td>1.2.2.62</td>
<td>27a6::23ee:51a</td>
</tr>
<tr>
<td></td>
<td>2.3.5.89</td>
<td>27a6::5542:225</td>
</tr>
<tr>
<td><a href="http://www.juniper.net">www.juniper.net</a></td>
<td>3.1.121</td>
<td>3090::e02:20f</td>
</tr>
<tr>
<td></td>
<td>3.20.796</td>
<td>3090::23ee:51a</td>
</tr>
<tr>
<td></td>
<td>4.6.5.89</td>
<td>2e66::3354:722</td>
</tr>
<tr>
<td></td>
<td>4.200.788</td>
<td>2e66::3354:722</td>
</tr>
</tbody>
</table>

When you define a policy that uses domain names as endpoints, and both domain names have IPv4 and IPv6 addresses, the device can establish secure communication between
the endpoints using either protocol. For example, the following commands define a policy between the domain names juniper.net and acme.com:

```plaintext
set address trust juniper www.juniper.net
set address untrust acme www.acme.com
set policy from trust to untrust juniper acme any permit
```

The two endpoints can exchange either type of traffic because the domain names each have IPv4 and IPv6 addresses.

However, if one domain name uses an IP stack that the other domain name does not, you must use NAT-PT to translate the source and destination addresses for transmitted DNS requests. For example, if juniper.net has only IPv6 addresses and acme.com has only IPv4 addresses, any service request sent from one to the other must undergo NAT-PT address translation.

In addition to translating the addresses, the NAT-PT DNS ALG also modifies the DNS request before forwarding it to another domain that has only IPv4 addresses. You can enable or disable the NAT-PT DNS ALG to modify DNS requests received from the IPv6 domain. If enabled, the NAT-PT DNS ALG modifies the DNS request for AAAA records going into the IPv4 domain. By default, this option is disabled, and the DNS request from the IPv6 domain undergoes only NAT-PT address translation. But if the DNS reply message indicates an error, the NAT-PT DNS ALG modifies the DNS request for AAAA records and sends it again to the IPv4 domain.

To enable the NAT-PT DNS ALG to modify DNS requests:

**WebUI**

Security > ALG > DNS: Enter the following, then click **Apply**:

- DNS Enable: (select)
- DNS Inhibit-AAAA-Request Enable: (select)

**CLI**

```plaintext
set alg dns inhibit-aaaa-request
save
```

In the following example, an IPv6 host (www.juniper.net) sends service requests to an IPv4 host (www.acme.com). It obtains the IPv4 address of the destination host from an IPv4 DNS server.

Figure 28: NAT-PT DNS Example
The device requires two policies:

- A policy that permits outgoing service requests and that performs NAT-PT on the source and destination addresses
- A policy that permits outgoing service requests from www.juniper.net to www.acme.com

In the following example, you configure a device to allow a Host A (www.juniper.net) to send service requests to a Host B (www.acme.com). The host domain names serve as the communication endpoints.

CHAPTER 6
IPv6 in an IPv4 Environment

6over4 tunneling is the process of encapsulating IPv6 packets within IPv4 packet headers so that IPv6 packets can traverse an IPv4 wide area network (WAN).

This chapter contains the following sections:

• Overview on page 95
• Configuring Manual Tunneling on page 96
• Configuring 6to4 Tunneling on page 99

Overview

6over4 tunneling is a way to send IPv6 traffic over an IPv4 wide area network (WAN) when you don’t need authentication and encryption for the exchanged traffic. For example, your organization might need to exchange traffic between island IPv6 networks over an IPv4 WAN. In this case, the security device provides only firewall services.

There are two kinds of 6over4 tunneling:

• Manual tunneling uses a manually configured, static remote-end tunnel termination point.
• 6to4 tunneling derives the remote-end tunnel termination point dynamically.

NOTE: For more information about 6to4 tunneling, refer to RFC 3056.

In most cases, the kind of tunneling to use depends on the kinds of routers and other devices present in a WAN infrastructure. For example, some ISPs (Internet Service Providers) provide manual tunnels to their customers as addendum services, and might have no need for 6to4 tunneling. In addition, there might be insufficient 6to4-configured relays in the IPv6 backbone to support 6to4 tunneling for your organization over the WAN.

6to4 tunneling can be appropriate if your organization needs to set up a one-to-many configuration, where one IPv6 network can access unspecified, multiple island IPv6 networks through multiple 6to4 relay routers. In such cases, 6to4 tunneling might be the best solution.
Configuring Manual Tunneling

Manual tunneling is best suited for applications that require strict control and usually provide more security than 6to4 tunneling. Manual tunneling does not require address translation because you specify explicitly the IPv4 address of the destination gateway.

IPv6 hosts use the tunnel to communicate with an IPv6 server over an IPv4 WAN backbone. The endpoints of the tunnel are interfaces on devices A and B.

When you configure a device for manual tunneling, the device encapsulates each outgoing IPv6 packet inside an IPv4 packet before transmitting it into IPv4 network space.

Figure 29 on page 96 shows a manual tunnel between two static, defined endpoints.

In the following example, you set up two devices (A and B) as endpoints for a manual 6to4 tunnel.

Configuring 6to4 Tunneling

When a device uses 6to4 tunneling, the device determines remote-end tunnel termination points (gateways) dynamically from routing table entries. In contrast with manual tunneling, which explicitly designates a single termination point for a VPN tunnel, 6to4 tunneling can allow any number of devices to serve as remote gateways for the tunnel. This allows one-to-many communication between a protected island IPv6 network and multiple external IPv6 networks.

For a network device to function as a 6to4 host, it must have an interface configured with a 6to4 address. Any IPv6 host without such an address is said to be native, or non-6to4. For example, if a host has interfaces with global aggregate IPv6 addresses but none with a 6to4 address, it is a native host. By contrast, if the host has an interface configured with a 6to4 address (whether or not it has other kinds of IPv6 addresses), it can function as a 6to4 host.

To set up a 6to4 tunnel between two devices, you must configure each communicating interface with a 6to4 address. The interfaces then serve as virtual border routers that handle the transition between IPv4 space and IPv6 space.

There are two kinds of 6to4 virtual router.

- **6to4 routers** function as border routers between IPv4 WANs and 6to4 networks.
- **6to4 relay routers** function as border routers between IPv4 WANs and native networks.

6to4 Routers

A 6to4 router is a router configured to support exchange of packets between 6to4 hosts and other 6to4 hosts over an IPv4 WAN. You can make a device function as a 6to4 router by configuring an IPv4 interface for 6to4.

When a packet from a 6to4 host passes through the device, the 6to4 router encapsulates the packet inside an IPv4 packet, then transmits it into the IPv4 network space. 6to4 routers can also receive such encapsulated packets, decapsulate them, and forward them to 6to4 devices.

Figure 30 on page 99 shows a 6to4 host sending a service request across an IPv4 WAN to another 6to4 host. The 6to4 router on Device A encapsulates the outgoing packets, and the 6to4 router on Device B decapsulates them.

Figure 30: 6to4 Routers
6to4 Relay Routers

A 6to4 relay router is a router configured to support exchange of packets between 6to4 hosts and native (non-6to4) hosts over an IPv4 WAN. As with 6to4 routers, you can make a device function as a 6to4 router by configuring an IPv4 interface to handle 6to4 tunneling. When a 6to4 relay router receives an incoming encapsulated 6to4 packet, the router decapsulates the packet and forwards it to the native destination host. When a native host transmits an outgoing packet, the 6to4 relay router encapsulates the packet inside an IPv4 packet, then transmits it into the IPv4 network space.

In Figure 31 on page 100, a 6to4 host sends a service request across an IPv4 WAN to a native (non-6to4) host. Device B decapsulates incoming packets, using the native IPv6 address as the destination address.

Figure 31: 6to4 Routers with Native Addresses

Tunnels to Remote Native Hosts

When a 6to4 host sends a service request to a remote native host, the device derives the remote termination point (gateway IPv4 address) from a routing table entry. Figure 32 on page 100 shows Device A sending an HTTP service request to the native server protected by Device B.

Figure 32: 6over6 Manual Tunneling

The 6to4 router on Device A derives the remote gateway IPv4 address (2.2.2.1) from a configured routing table gateway entry 2002:0202:201:2:9876:abff:fece5432. (For this example, the MAC address of the remote gateway interface is 9876abcd5432.)

A device addresses packets that pass between a 6to4 host and a native host over an IPv4 WAN in the following manner:
1. The IPv6 host (Host A) generates an IPv6 packet and sends it to Device A.
2. Device A, a 6to4 router, encapsulates the outgoing IPv6 packet inside an IPv4 packet and sends it out the tunnel interface over the IPv4 WAN to Device B.
3. Device B decapsulates the packet and forwards it to Host B.
4. Host B generates a reply packet. Device B encapsulates it and forwards it to Device A.
5. Device A receives the encapsulated reply packet through the tunnel interface. Device A decapsulates the packet and forwards it to Host A.

In this example, you configure a device to send HTTP requests from IPv6 hosts to a native host (an HTTP server) over an IPv4 WAN infrastructure.

    set policy from untrust to trust R_Clients L_Server http permit

**Tunnels to Remote 6to4 Hosts**

When a 6to4 host sends a service request to remote a 6to4 host, the device derives the remote termination point (gateway IPv4 address) from the destination IP address of the outgoing request packet.

*Figure 33 on page 104* shows Host A sending an HTTP service request to a server protected by Device B.
In this example, the 6to4 destination address of the outgoing packet is 2002:0202:0201:3:5678:abff:fedc:2345, which is the address of 6to4 Host B. The 6to4 router (on Device A) derives the remote gateway IPv4 address (2.2.2.1) from this destination address.

A device addresses packets that pass between a 6to4 host and another 6to4 host over an IPv4 WAN in the following manner:

1. The IPv6 Host A generates an IPv6 packet and sends it to Device A.
2. Device A derives the IPv4 destination address of the remote gateway (2.2.2.1) from the destination address of the outgoing packet.
3. Device A encapsulates the outgoing 6to4 packet inside an IPv4 packet and sends it out the tunnel interface into Zone B.
4. Device B decapsulates the packet and forwards it to Host B.
5. Host B generates a reply packet.
6. Device B encapsulates it and forwards it to Device A.

In this example, you configure a device to send HTTP requests from IPv6 hosts to an IPv6 server over an IPv4 WAN infrastructure.

CHAPTER 7

IPsec Tunneling

6in6, 4in6, and 6in4 tunneling allow you to create virtual private networks. These mechanisms automatically perform packet encapsulation and ensure secure packet exchange over the WAN.

This chapter contains the following sections:

- Overview on page 107
- IPsec 6in6 Tunneling on page 107
- IPsec 4in6 Tunneling on page 111
- IPsec 6in4 Tunneling on page 115
- Manual Tunneling with Fragmentation Enabled on page 119

Overview

ScreenOS allows you to create virtual private networks (VPNs). A VPN connection can link two local area networks (LANs) or a remote dialup user with a LAN. The traffic that flows between these two points passes through shared resources such as routers, switches, and other network equipment that make up the public WAN. To secure VPN communication traffic, the two participants create an IP security (IPsec) tunnel.

You create policies to provide IPsec security services such as authentication and encryption or use Network Address Translation (NAT) to define private address space. For more information about NAT, see Address Translation. For information about security concepts and VPNs, see Fundamentals and Virtual Private Networks.

This chapter includes configuration examples that use VPN tunnels in a purely IPv6 environment and other scenarios for IPv4 or IPv6 island networks or hosts.

IPsec 6in6 Tunneling

6in6 tunneling is a method to encapsulates IPv6 packets inside IPv6 packets and is used where the exchanged information must travel within an IPv6 domain and requires protection to ensure data confidentiality and integrity.

Use IPsec in combination with 6in6 tunneling when you need to establish secure communication between IPv6 hosts and other IPv6 hosts over an IPv6 infrastructure,
For example, you might need to exchange secured traffic between an IPv6 network and an IPv6 server over an IPv6 WAN.

**Figure 34 on page 108** shows an IPv6 host sending an HTTP service request to an IPv6 Web server over an IPv6 WAN infrastructure. Both devices have policies that use IPsec security.

**Figure 34: IPsec with 6in6 Tunnel Example**

The following lists the steps to how a device configured for IPv4-to-IPv6 host mapping translates the source and destination addresses of an outgoing service request packet.

1. Host A generates the service request packet and assigns it the IPv6 destination address (3abc::9).
2. Device A encapsulates the entire IPv6 packet inside of another IPv6 packet. It then sends it out the tunnel interface to Device B.
3. The remote IPv6 host device sends a reply packet.
4. Device A decapsulates the replay packet and sends it to the IPv6 host.

In the following example, you set up IPsec policies that allow HTTP communication between an IPv6 network and a remote IPv6 network or a subnet. The traffic passes over an IPv6 WAN environment.

**IPsec 4in6 Tunneling**

4in6 tunneling allows you to establish communication between IPv4 networks over an IPv6 backbone. This transition mechanism uses IPsec to encapsulate packets exchanged between IPv4 networks over an IPv6 backbone. Encapsulation makes exchanged packets routable across the IPv6 network space.

In addition to encapsulating the packets, IPsec can perform authentication and encryption.

Figure 35 on page 111 shows an IPsec tunnel between remote IPv4 networks. In this example, you define a tunnel interface on each gateway device and bind the tunnel to a zone that borders IPv6 network space.

---

**Figure 35: IPsec 4in6 Tunnel Example**

A device addresses packets that pass between an IPv4 host in an IPv4 island network and another IPv4 host over an IPv6 WAN backbone in the following manner:

1. Host A generates an IPv6 service request packet and addresses it to Host B. The packet goes from Zone A to Zone B.
2. Device A encapsulates the outgoing IPv4 packet inside an IPv6 packet and sends it out the tunnel interface.
3. Device B decapsulates the packet and forwards it to Host B.
4. Device B generates a reply packet, encapsulates it, and forwards it to Device A.
5. Device A receives the encapsulated reply packet through the tunnel interface. Device A decapsulates the packet and forwards it to Host A.

The steps to set up 4in6 tunneling are as follows:

1. Configure an interface for communication with the protected IPv4 network.
   • Bind the interface to a zone (typically the Trust zone).
   • Assign the interface an IPv4 address and subnet mask.
2. Configure an interface for communication over the IPv6 WAN.
   • Bind the interface to a zone (typically the Untrust zone).
   • Configure the interface for IPv6 host mode.
   • Assign the interface an IPv6 address and subnet mask.
   • Create a tunnel interface (unnumbered) in the zone and bind it to the IPv6 interface.
   • Configure the tunnel interface for IPv6 host mode.
3. Set up interfaces on the peer device in a similar manner.
4. Set up IPsec between the peer devices. For more examples of IPsec, see Virtual Private Networks.
5. On each device, create address book entries that identify the IPv6 host, subnet, or network.
6. Set up routing entries that allow the hosts to access each other.
7. Set up security policies.

In the following example, you create an IPsec tunnel between IPv6 endpoints. IPv4 devices behind Device A transmit service requests hosts behind Device B. Device A use IPsec to encapsulate the service request packets inside IPv6 packets. Device B receives and decapsulates the packets.

**IPsec 6in4 Tunneling**

You can use IPsec tunneling, which supports authentication and encryption, to encapsulate packets as the security device transmits them between remote IPv6 island networks over an IPv4 WAN.

**Figure 36 on page 115** shows an IPsec tunnel between remote IPv6 island networks. In this example, you first define a tunnel interface on each gateway device; then you bind the tunnel to a zone that borders IPv4 network space.

**Figure 36: Tunnel Interface and Zone Example**

A device addresses packets that pass between a host in an IPv6 island network and another IPv6 host over an IPv4 WAN backbone in the following manner:

1. Host A generates an IPv6 service request packet and addresses it to Host B. The packet goes from Zone A to Zone B.
2. Device A encapsulates the outgoing IPv6 packet inside an IPv4 packet and sends it out the tunnel interface into Zone B.
3. Device B decapsulates the packet and forwards it to Host B.
4. Device B generates a reply packet, encapsulates it, and forwards it to Device A.

5. Device A receives the encapsulated reply packet through the tunnel interface. Device A decapsulates the packet and forwards it to Host A.

In most cases, the necessary setup tasks are as follows:

1. Configure an interface for communication with the protected island IPv6 network.
   - Bind the interface to a zone (typically the Trust zone).
   - Configure the interface for IPv6, host mode.
   - Assign the interface a global unicast prefix. (For information about global unicast addresses, see “Address Types” on page 4.)

2. Configure an interface for communication over the IPv4 WAN.
   - Bind the interface to a zone (typically the Untrust zone).
   - Assign the interface an IPv4 address and subnet mask.
   - Create a tunnel interface (unnumbered) in the zone and bind it to the IPv4 interface.

3. Follow steps 1 and 2 to set up interfaces on the peer device.

4. Set up IPsec between the peer devices. For more information about IPsec, see Virtual Private Networks.

5. On each device, create address book entries that identify the IPv6 host, subnet, or network.

6. Set up routing entries that allow the hosts to access each other.

7. Set up security policies.

In the following example, you create an IPsec tunnel between IPv4 endpoints. IPv6 devices behind Device A transmit service requests to hosts behind Device B. Device A use IPsec to encapsulate the service request packets inside IPv4 packets. Device B receives and decapsulates the packets. See Figure 36 on page 115.

The devices perform Phase 1 of the AutoKey IKE tunnel negotiation as follows:

- RSA authentication
- Diffie-Hellman Group 2
- AES128 encryption algorithm
- SHA hashing algorithm

The devices perform Phase 2 of the tunnel negotiation uses the Standard proposal.

- Diffie-Hellman Group 2
- ESP (Encapsulating Security Payload) tunneling
- 3DES encryption algorithm
- SHA hashing algorithm

CHAPTER 8

IPv6 XAuth User Authentication

This chapter describes IPv6 user authentication and Dead Peer Detection (DPD) and provides configuration examples. It contains the following sections:

- Overview on page 127
- Configuration Examples on page 133

Overview

ScreenOS XAuth for IPv6 allows you to authenticate individual users and user groups after Phase 1 IKE negotiations.

You can use XAuth to authenticate remote virtual private network (VPN) users (or user groups) individually instead of only authenticating VPN gateways and/or devices or to assign TCP/IP configuration information, such as IP address, netmask, DNS server, and WINS server assignments.

RADIUSv6

ScreenOS supports RADIUSv6, the next-generation version of RADIUS. When a device functions as an XAuth server, it sends a username and password to a RADIUS server enabled for IPv4, IPv6, or both.

NOTE: For more information about RADIUS and IPv6, refer to RFCs 3162 and 2882.

The next sections show various scenarios. Configuration examples follow these scenarios.

Single Client, Single Server

Figure 38 on page 128 shows a single client device and a single server interacting with a RADIUS server performing XAuth authentication.
Figure 38: RADIUS with a Single Client and Single Server

The RADIUS server resides in the Trust zone of the XAuth server. Each protected subnet can contain more than a single protected host, but the figure shows only one.

Multiple Clients, Single Server

Figure 39 on page 128 shows multiple client devices and a single server interacting with a RADIUS server performing XAuth authentication.

Figure 39: RADIUS with Multiple Clients and a Single Server

The RADIUS server resides in the Trust zone of the server. Each client device protects a different subnet. Each protected subnet can contain more than a single host, but the figure only shows one.

Single Client, Multiple Servers

Figure 40 on page 129 shows a single client device and a single server interacting with multiple RADIUS servers.
Multiple Hosts, Single Server

Figure 41 on page 129 shows a single client device (Device 1) protecting multiple hosts and a single server (Device 2) interacting with a RADIUS server.

The RADIUS server resides in the Trust zone of the security server.

IPsec Access Session Management

You can use several security devices to allow user networks to access outside networks by setting up one or more local customer premises equipment (CPE) routers and one or more gateway routers. To protect packets transmitted over the access network, the CPE and gateway devices can establish an IPsec tunnel. The gateway, together with the RADIUS server manages and records accounting for the network access sessions.

IPsec Access Session

The time interval during which a network access session exists is called an IPsec Access Session (IAS). The IAS time interval begins when the first end user connects to the access network and ends when the last user disconnects from the network. Figure 42 on page 130 shows how an ISP might use security devices as CPE and gateway routers.
To initiate an IAS, the CPE device performs a Phase 1 Internet Key Exchange (IKE) and at least one Phase 2 IKE.

**NOTE:** For more information about ScreenOS security concepts and IKE, see *Internet Protocol Security*.

Each IAS has the following characteristics.

- A CPE device can have only one IAS Phase 1 Security Association (SA) for each IP address. For example, if the CPE device has three IPv6 addresses, it can host three Phase 1 SAs. However, there might be multiple Phase 2 SAs for each Phase 1 SA.
- During an IAS lifetime, the CPE and gateway devices might perform many IPsec operations, such as IKE Phase 1 and Phase 2 rekeying.
- During the IAS lifetime, the CPE initiates Phase 1 SA rekeys whenever the Phase 1 session expires.
- During the IAS lifetime, the CPE must initiate a new Phase 2 SA rekey *before* a Phase 2 session expires to ensure that SA is always on.

While it exists, each IAS contains and uses the following components:

<table>
<thead>
<tr>
<th>Information Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPE IPv6 Address</td>
<td>The address of the CPE device. The address is globally unique; that is, there cannot be more than one IAS with the same CPE IP address.</td>
</tr>
<tr>
<td>IKE Phase 1 ID</td>
<td>The ID that identifies the Phase 1 gateway for the IAS. This ID can consist of any of the following:</td>
</tr>
<tr>
<td></td>
<td>• An alphanumeric string that identifies the gateway device</td>
</tr>
<tr>
<td></td>
<td>• The ASN1 domain name of the gateway device</td>
</tr>
<tr>
<td></td>
<td>• The Fully Qualified Domain Name (FQDN) of the gateway device</td>
</tr>
<tr>
<td></td>
<td>• The IP address (IPv4 or IPv6) of the gateway device</td>
</tr>
<tr>
<td></td>
<td>• The user-Fully Qualified Domain Name (u_FQDN) of the gateway device</td>
</tr>
<tr>
<td>XAuth User Name</td>
<td>The name of the XAuth user.</td>
</tr>
<tr>
<td>IKE Phase 1 Cookie Pair</td>
<td>The IKE Phase 1 SA cookies, which show the Phase 1 SA associated with the IAS.</td>
</tr>
</tbody>
</table>
The number of Phase 2 SAs that currently exist in the IAS. For the IAS to exist, there must be one or more Phase 2 SAs.

Number of Phase 2 SAs

The IP4 address assigned from the gateway to the CPE during the IKE mode configuration phase.

Assigned IP address

Security Parameter Index (SPI) values, including both new and old SPIs.

Phase 2 SA SPIs

The time the IAS began.

IAS Start Time

When a CPE gateway device initiates an IAS successfully, it starts RADIUS accounting for that IAS. When a Phase 2 SA expires or fails, the CPE device must establish another SA to continue secure communication with the gateway device. How the RADIUS server handles a Phase 2 rekey operation depends on whether IAS functionality is currently enabled or disabled.

When the IAS feature is disabled, the RADIUS accounting session starts over after the CPE establishes a new SA. Each time a Phase 2 session fails or times out, a new accounting session is necessary; and the RADIUS server must generate multiple billings (and, in some cases, other account-related features).

When the IAS feature is enabled, however, the original RADIUS accounting session resumes after each Phase 2 SA rekeying operation occurs. This allows the RADIUS server to maintain a single continuous accounting session to simplify billing and other accounting-related features.

Enabling and Disabling IAS Functionality

To enable the CPE gateway device for IAS functionality, enter the following command:

```
set ipsec-access-session enable
```

To disable the CPE gateway device for IAS functionality, enter the following command:

```
unset ipsec-access-session enable
```

Releasing an IAS Session

You can release an IPsec access session with the `clear ike all` command.

Limiting IAS Settings

The following settings limit the number of concurrently active IASs:

- The `maximum` specifies the maximum number of concurrent IASs the device allows. The default is 5000 sessions, and the range is from 0 to 5000 sessions.

To configure this limitation, enter the following command:

```
set ipsec access-session maximum maximum_number
```
• The lower IAS threshold specifies the minimum number of concurrent IASs the device allows before triggering a SNMP trap. The default is 1000 sessions, and the range is from 1 to 5000 sessions. This value must be less than the upper-threshold value.

To configure this limitation, enter the following command:

```
set ipsec access-session lower-threshold minimum_number
```

• The upper IAS threshold specifies the minimum number of concurrent IASs the device allows before triggering a SNMP trap. The default is 1000 sessions, and the range is from 1 to 5000 sessions. This value must be greater than the lower-threshold value.

To configure this limitation, enter the following command:

```
set ipsec access-session upper-threshold maximum_number
```

Dead Peer Detection

Dead Peer Detection (DPD) is a protocol that verifies the existence and liveliness of other IPSec peer devices when no incoming IPSec traffic from peers is received during a specified interval.

A device performs DPD by sending encrypted IKE Phase 1 notification payloads (R-U-THERE) to peers and waiting for DPD acknowledgements (R-U-THERE-ACK) from its peers. The device sends an R-U-THERE request only if it has not received any traffic from the peer during a specified DPD interval. If a DPD-enabled device receives traffic on a tunnel, it resets the R-U-THERE counter for that tunnel to start a new interval. If the device receives an R-U-THERE-ACK from the peer device during this interval, it determines the peer to be alive. If the device does not receive an R-U-THERE-ACK response during the interval, it determines the peer to be dead.

The device removes the Phase 1 SA and all Phase 2 SAs for dead peers. In previous ScreenOS releases, the active tunnel could not fail over to another tunnel and gateway in the group. To maintain continuous connectivity even if a peer goes dead, in the current ScreenOS release the dead peer fails over the tunnel to another group member with the second highest weight. Meanwhile, the device attempts to renegotiate the tunnel with the peer identified as dead. Once the tunnel is successfully negotiated, the tunnel automatically fails back to the first member. The weighting system always causes the best ranked gateway in the group to handle the VPN data whenever possible.

NOTE: The device also renegotiates the tunnel if the lifetime of the Phase 1 SA is about to expire.

You can configure the following DPD parameters with the CLI or the WebUI:

• The interval parameter specifies the DPD interval. This interval is the amount of time (expressed in seconds) the device allows to pass before considering a peer to be dead. A setting of zero disables DPD.

• The always-send parameter instructs the device to send DPD requests regardless of whether there is IPSec traffic with the peer.
• The retry parameter specifies the maximum number of times to send the R-U-THERE request before considering the peer to be dead. As with an IKE heartbeat configuration, the default number of transmissions is 5 times, with a permissible range from 1 to 128 attempts.

• The reconnect parameter instructs the device to renegotiate the tunnel at the specified interval with the peer considered to be dead. As with an IKE recovery configuration, the minimum setting is 60 seconds. You can set the interval at any value between 60 and 9999 seconds.

NOTE: You can enable DPD or IKE heartbeat but not both. If you attempt to configure DPD after enabling the IKE heartbeat, the security device generates the following error message:

IKE: DPD cannot co-exist with IKE heartbeat.

The device generates a similar error if you attempt to configure an IKE heartbeat after enabling DPD.

Configuration Examples

This section contains examples for RADIUS, IAS, and DPD.

NOTE: The WebUI section of each example lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

XAuth with RADIUS

Figure 43 on page 133 shows device A performing XAuth authentication on users in its local network and a device B using a RADIUS server to perform XAuth in response to authentication through an IKE tunnel.

Figure 43: XAuth Example

WebUI (XAuth Client)

   set ike gateway server_gw6 cert peer-cert-type x509-sig
   set ike gateway server_gw6 xauth server xauth-rad query-config

**RADIUS with XAuth Route-Based VPN**

In this example, an XAuth client performs authentication and authorization using XAuth and RADIUS, with prefix delegation and mode config, over a route-based VPN. This delegates the IP address obtained from the RADIUS server to a tunnel interface on XAuth client (unless the client specifies another interface).

---

**NOTE:** The VPN in this example is route-based. In a policy-based VPN, or if there is a framed netmask other than “/32”, the device installs the IP address on the tunnel interface.

---

See Figure 38 on page 128.

The steps to configure this example are as follows:
1. Configure an XAuth client to perform IPv6 CPE operation (for VPN).
2. Configure an XAuth IPv6 gateway (for VPN) to perform server configuration.
3. Enable an XAuth server (RAD1) with IP address 50.1.1.3. Give RADIUS a shared secret, with port number 1812 for RADIUS.
4. Specify a valid username (PC1) and a valid password (PC1) for the user from the XAuth client.

RADIUS with XAuth and Domain Name Stripping

In the following example, you use the domain name checking feature, which checks the
domain name (starting from the right most character to the left most until it finds the
separator character). This feature enables the device to allow users from a particular
domain only.

See Figure 38 on page 128.

The steps to configure this example are as follows:

1. Enable IPv6 CPE configuration (for VPN) and configure XAuth on the XAuth client.
2. Enable IPv6 gateway configuration (for VPN) on the XAuth server.
3. Enable the XAuth server as Radius RAD1, with IP address 50.1.1.3. Give it RADIUS shared
   secret (juniper) and port number (1812).
4. Enter commands that do the following:
   • On the XAuth client: Provide the username (PC1@juniper.net) and password (PC1) for
     that user.
   • On the XAuth server:
     • Configure the username that comes from the XAuth client to be PC1@juniper.net.
     • Allow only users from domain "juniper.net."
     • Strip the username from right to left until one separator character (@) is found.

IP Pool Range Assignment

A device assigns a user an IP address from its local IP pool when a RADIUS server returns a framed-ip-address of 255.255.255.254. If all the IP addresses in range contained in the default IP pool are used up, the device uses IP addresses from the next IP range.

See Figure 39 on page 128.

The steps to configure this example are as follows:

1. Enable IPv6 CPE configuration (for VPN) and XAuth client configuration on Client 1, Client 2, and Client 3.

2. On the XAuth server:
• Enable the IPv6 gateway configuration (for VPN).

• Configure a tunnel for Client 1, Client 2, and Client 3.

• Enable XAuth server (RAD1) with IP address 50.1.1.3. Specify the RADIUS shared secret (juniper) and port number (1812).

• Define a local IP pool (P1) containing two IP ranges.
  - 80.1.1.1 to 80.1.1.2
  - 80.1.1.3 to 80.1.1.4.

• Enable the default XAuth IP pool (P1).

• Specify valid usernames (PC4) and valid passwords (PC4) for those users from the XAuth clients (Device 1, Device 2, and Device 3).

3. On the RADIUS server, insert a framed IP address with a subnet mask of 255.255.255.254 for the user PC4.

**WebUI (XAuth Client 1, XAuth Client 2, and XAuth Client 3)**

**NOTE:** The WebUI paths are the same for each XAuth client. The values you enter for some fields differ. See the CLI commands for the correct values.

set ike gateway NS2_NS3 add 2ddd::1 outgoing-interface ethernet3 local-add 2ddd::2
  preshare abc123 sec-level standard
set ike gateway NS2_NS4 add 3ddd::1 outgoing-interface ethernet4 local-add 3ddd::2
  preshare abc123 sec-level standard
set ike gateway NS2_NS1 xauth server RAD1 query-config user PC4
set ike gateway NS2_NS3 xauth server RAD1 query-config user PC4
set ike gateway NS2_NS4 xauth server RAD1 query-config user PC4

7. VPN
set vpn NS2toNS1 gateway NS2_NS1 sec-level standard
set vpn NS2toNS1 bind interface tunnel.1
set vpn NS2toNS3 gateway NS2_NS3 sec-level standard
set vpn NS2toNS3 bind interface tunnel.2
set vpn NS2toNS4 gateway NS2_NS4 sec-level standard
set vpn NS2toNS4 bind interface tunnel.3

8. Policies
set policy id 1 from untrust to trust any-ipv6 any-ipv6 any permit
set policy id 2 from trust to untrust any-ipv6 any-ipv6 any permit

RADIUS Retries

In an environment with a single XAuth client and XAuth server with multiple RADIUS servers, you can configure the number of RADIUS server retries before the XAuth server tries a backup server. The default number of retries is 3 (4 total). For example, if you configure the device to 20 retries, the device sends a total of 21 requests to the primary RADIUS server before trying the backup server.

In this example, based on the topology shown in Figure 40 on page 129, only shows the RADIUS configuration for the XAuth server.
WebUI (XAuth Server, RADIUS Configuration)

Configuration > Auth > Auth Servers > New

Configuration > Auth > Auth Servers > Edit

CLI (XAuth Server, RADIUS Configuration)

```bash
set auth-server RAD1 id 1
set auth-server RAD1 server-name 50.1.1.3
set auth-server RAD1 backup1 50.1.1.5
set auth-server RAD1 account-type xauth
set auth-server RAD1 radius secret juniper
set auth-server RAD1 radius port 1812
set auth-server RAD1 radius retries 20
```

Calling-Station-Id

The Calling-Station-Id attribute cannot be seen in the Access-Request packet and in the Accounting-Request packet by default. You can configure this attribute to appear in packets. The ike-ip address will be sent in the access request packet.

In the following example based on Figure 38 on page 128, you configure an XAuth server to include the Calling-Station-Id attribute in packets. This example only shows the RADIUS configuration for the XAuth server.

WebUI (Device 2)

Configuration > Auth > Auth Servers > New

Configuration > Auth > Auth Servers > Edit

CLI (Device 2)

```bash
set auth-server RAD1 id 1
set auth-server RAD1 server-name 50.1.1.3
set auth-server RAD1 backup1 50.1.1.5
set auth-server RAD1 account-type xauth
set auth-server RAD1 radius secret juniper
set auth-server RAD1 radius port 1812
set auth-server RAD1 radius attribute calling-station-id
```

IPsec Access Session

Figure 44 on page 149 shows four devices, configured as CPE routers, interacting with an upstream gateway router (Device 5) through a downstream router (Device 2). In all cases, ipsec-access-session feature is enabled, which allows the RADIUS server to maintain a single continuous RADIUS accounting session.
In the following example, four CPEs establish tunnels to the same interface on the Gateway router (ethernet1, IP address 2aad::2). You initiate an IAS session on the Gateway, which allows the four different XAuth users (one on each CPE router), identifying themselves using separate usernames and passwords.

**NOTE:** The WebUI section lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

The basic steps to perform this example are as follows:

1. Configure all four CPE devices, the router, and the Gateway as described in the CLI below.
2. From each of the four CPEs, send an XAuth user (PC1, PC2, PC3, and PC11 with passwords PC1, PC2, PC3, and PC11, respectively). In addition, configure all the CPEs as XAuth clients.
3. From all the CPEs send domain names as "juniper.net" and configure VPN for aggressive mode negotiations.
4. On the Gateway, do the following:
   a. Perform the XAuth server configuration.
   b. Specify the RADIUS shared secret as juniper, and specify the port as 1812.
   c. Add a user group (group1) and add user (n1) with domain name "juniper.net" and share limit 10.

On the RADIUS server, do the following:
a. Add users PC1, PC2, PC3, and PC4 and specify passwords PC1, PC2, PC3, and PC4 respectively.
b. Specify all the required attributes (such as framed-ip-address) to all the users.

Dead Peer Detection

Figure 45 on page 157 shows two devices configured for Dead Peer Detection (DPD).

Figure 45: Dead Peer Detection Example

NOTE: The WebUI section lists only the navigational paths to the device configuration pages. For specific values, see the CLI section that follows it.

On Device 1:

- Configure Trust and Untrust interfaces of Device 1 as an IPv6 router.
  - Configure the Trust interface to advertise prefix 2aaa::.
  - Configure the Untrust interface to advertise prefix 2bbb::.

- Configure an IKE gateway.

- Configure a VPN.

- Set the DPD interval time to 15 seconds and the retry setting to 10 retries.

On Device 2:

- Configure Untrust interface of as an IPv6 host so it can accept RAs.

- Configure the Trust interface as an IPv6 router, advertising prefix 3bbb::.

- Configure an IKE gateway.

- Configure a VPN.

NOTE: Optionally, you can set DPD Always Send by entering the set ike gateway ton4 dpd always-send command.

PART 2

Appendix

- Switching on page 163
Switching

You can use the security device as a switch to pass IPv6 traffic along a path. To do this, you must place the device in transparent mode. For more information about transparent mode, see *Fundamentals*.

Table 6 on page 163 lists the ScreenOS commands that can allow IPv6 traffic and other non-IP traffic to pass through a security device operating in transparent mode.

### Table 6: Transparent Mode Commands to Bypass Non-IP Traffic

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>set interface vlan1 bypass-non-ip</code></td>
<td>Allows all Layer 2 non-IP traffic to pass through the security device.</td>
</tr>
<tr>
<td><code>unset interface vlan1 bypass-non-ip</code></td>
<td>Blocks all non-IP and non-ARP unicast traffic (default behavior).</td>
</tr>
<tr>
<td><code>unset interface vlan1 bypass-non-ip-all</code></td>
<td>Overwrites the <code>unset interface vlan1 bypass-non-ip</code> command when both commands appear in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>If you previously entered the <code>unset interface vlan1 bypass-non-ip-all</code> command, and you now want the device to revert to its default behavior of blocking only the non-IP and non-ARP unicast traffic, you first enter the <code>set interface vlan1 bypass-non-ip</code> command to allow all non-IP and non-ARP traffic, including multicast, unicast, and broadcast traffic to pass through the device. Then you enter the <code>unset interface vlan1 bypass-non-ip</code> command to block only the non-IP, non-ARP unicast traffic.</td>
</tr>
<tr>
<td><code>set interface vlan1 bypass-others-ipsec</code></td>
<td>Allows a device to pass IPsec traffic without attempting to terminate it, use the command. The device then allows the IPsec traffic to pass through to other VPN termination points.</td>
</tr>
</tbody>
</table>

- DIP, from IPv6 to IPv4......................................................82
- dynamic IP (DIP)..............................................................81
- IPv4 hosts to a single IPv6 host...........................................90
- IPv4 hosts to multiple IPv6 hosts........................................88
- IPv6 hosts to a single IPv4 host............................................86
- IPv6 hosts to multiple IPv4 hosts........................................84
- MIP from IPv4 to IPv6........................................................83
- NAT-PT..............................................................................81
- outgoing service requests................................................81, 84
- source address translation................................................82
- when to use.........................................................................81

### Next-hop gateway.................................................................29

### P
- Point-to-Point Protocol (PPP)..............................................49
- Point-to-Point Protocol over Ethernet (PPPoE).....................49
- PPPoE - Point-to-Point Protocol over Ethernet.......................49
- prefix lists........................................................................12
- probe..................................................................................29
- protocols
  - IGP................................................................................54
  - PPP.................................................................................49
  - PPPoE............................................................................49

### R
- RA..................................................................................12
- RADIUSv6........................................................................127
- reachability states..............................................................14
- reachability states, transitions............................................16
- remote termination point....................................................100, 103
- request packets, outgoing from IPv6 to IPv4.........................83
- Retransmission Time............................................................30
- RIP
  - configuration....................................................................56
  - flooding, protecting against............................................62
  - global parameters...........................................................58
  - instances, creating in VR..................................................56
  - interface parameters........................................................52
  - interfaces, enabling on.....................................................57
  - neighbors, filtering..........................................................60
- RIP routes
  - default, rejecting...........................................................59
  - redistributing.................................................................61
- RIP, viewing
  - database.........................................................................67
  - neighbor information.......................................................69
  - protocol details...............................................................68
- RIPng...............................................................................53, 54
  - interface cost metric........................................................63
  - metric calculation............................................................63
  - offset metric...................................................................63
  - route metric....................................................................63
  - route redistribution...........................................................54
- Router Advertisement (RA).................................................12
- router mode........................................................................55
- Router Solicitation (RS).......................................................12
- routers
  - upstream..........................................................................38
  - virtual...............................................................................53
- RSA authentication.............................................................116

### S
- service requests, outgoing..................................................84, 86
- Site-Local Aggregator (SLA).................................................36, 39
- source address translation......................................................82
- state transitions
  - endpoint host................................................................16
  - next-hop gateway router.................................................16
  - static entry.......................................................................18
  - tunnel gateway...............................................................17
- stateless address autoconfiguration.......................................11

### T
- Top-Level Aggregator (TLA)...............................................36
- tunnel termination points....................................................99

### U
- upstream routers...................................................................38

### V
- virtual routers.......................................................................53
- virtual routers, RIP..............................................................56

### W
- WebUI................................................................................30
- WebUI, on sample client, downstream router.........................40
- WINS server.........................................................................127

### X
- XAuth
  - authentication..................................................................133
  - when to use.......................................................................127
