AI Data Center Network with Juniper Apstra, Nvidia GPUs, ConnectX NIC, and Weka Storage—Juniper Validated Design (JVD)

Juniper Networks Validated Designs provide a comprehensive, end-to-end blueprint for deploying Juniper solutions in your network. These designs are created by Juniper's expert engineers and tested to ensure they meet your requirements. Using a validated design, you can reduce the risk of costly mistakes, save time and money, and ensure that your network is optimized for maximum performance.

About this Document

This document describes the design requirements and implementation of an AI cluster infrastructure connecting Nvidia A100 and H100 GPU servers and Weka Storage systems, based on AI-optimized Juniper Data Center Juniper switches, which are configured and managed by Juniper Apstra and Terraform automation.

All validation tests were conducted in Juniper's AI Innovation Lab in Sunnyvale, CA, USA. In this open lab, Juniper collaborates closely with customers and technology partners to develop AI solutions and test deployments for a range of AI applications and models.

The AI Innovation Lab allows customers to see AI training and inference in action, running on an NVIDIA GPU and WEKA Storage cluster. Juniper performs these tests running both customer-specific models as well as those from MLCommons for MLPerf performance benchmarking and comparisons.

Solution Benefits

Juniper Networks has excelled in building and supporting AI networks following a scalable, robust, and automated approach suitable for a range of cluster sizes. Unlike proprietary solutions that lock in enterprises and can stifle AI innovation, Juniper's standards-based solution assures the fastest innovation, maximizes design flexibility, and prevents vendor lock-in on the Frontend, GPU Backend, and Storage Backend AI fabric networks.

The Juniper Validated Design (JVD) for AI describes a structured approach for deploying high-performance AI training and inference networks that minimize job completion time and maximize GPU

performance. Additionally, it incorporates industry best practices, and leverages Juniper's extensive expertise in building high-performance data center networks.

This design in this JVD employs a 3-stage Clos IP fabric architecture utilizing Juniper QFX and PTX switches. It integrates NVIDIA GPUs and WEKA storage and is deployed and managed using Juniper's Apstra software and Terraform Automation, incorporating best practices and Juniper's extensive experience in building Data Center networks.

The integration with Juniper's Apstra software and Terraform enables customers to orchestrate the network infrastructure systematically, without requiring in-depth knowledge of the products and technologies involved. This allows customers to easily build high-capacity, easy-to-operate network fabrics that deliver high performance, increased reliability, which result in optimal JCT (Job Completion Time) and maximized GPU utilization in the AI cluster.

The solution has been extensively tested and thoroughly documented by Juniper subject matter experts, resulting in a validated design that is easy to follow, guarantees successful implementation, and simplified management and troubleshooting tasks. This document provides comprehensive guidance on how to deploy this solution, with clear descriptions of its components and step by step instructions to connect and configure them.

Juniper Validated Design Benefits

JVDs are prescriptive blueprints for building data center fabrics using repeatable, validated, predictable, and well documented network architecture solutions with guidelines for a successful deployment. Each solution has been designed, fully tested, and documented by Juniper Networks experts with all the necessary implementation details, including hardware components, software versions, connectivity, and configuration steps.

To become a validated solution (JVD) and be approved for release, a solution must pass rigorous testing with real-world workloads and applications. All features must satisfy operational and performance criteria in real-world scenarios. Testing not only includes validating the design topology and configuration steps, but also that all products in the JVD work together as expected, thereby mitigating potential risks while deploying the solution.

The core benefits of JVDs solutions can be summarized as:

- **Qualified Deployments**—Qualified network design blueprints for data center fabrics, that follow best practices and meet the requirements of each specific use case, and make the solution deployment quicker, simpler, and more reliable.

- **Scalable**—Solutions that can scale beyond the initial design and support the adoption of different hardware platforms based on customer requirements, and customers' feedback can meet the needs of most Juniper's data center customers.
- **Risk Mitigation**— Prescriptive implementation guidelines guarantee that you have the right products, right software versions, optimal architecture, and deployment steps.
- Systematically Verified—Tested solutions using a suite of automated testing tools to validate the performance and reliability of all the components.
- **Predictability**— Detailed testing and careful documentation of the solution, including the capabilities and limitations of its components, guarantees that the solution will operate as expected when implemented according to the JVD guidelines.
- **Repeatability**— Unlocked value with repeatable network designs due to the prescriptive nature of JVD designs as well as their applicability to common use cases in the data center environment. All JVD customers benefit from lessons learned through lab testing and real-world deployments.
- **Reliability**— Tested with real traffic, JVD solutions are qualified to operate as designed after deployment and with real-world traffic.
- **AcceleratedDeployment**— Ease installation with step-by-step guidance automation, and prebuilt integration simplifies, and accelerates deployment, while reducing risks.
- **AcceleratedDecision-Making**— Predefined combination of products, software, and architecture removes the need to spend time comparing products, and deciding how the network should be built, allowing to bridge business and technology requirements faster and also reducing risks.
- **BestPracticeNetworks**— Better outcomes for a better experience. Juniper Validated Designs have known characteristics and performance profiles to help you make informed decisions about your network.

Juniper Apstra Benefits

Juniper Validated Designs in the data center start with the Apstra software, a multi-vendor, intent-based networking system (IBNS) that provides closed-loop automation and assurance. Apstra translates vendor-agnostic business intent and technical objectives to essential policy and device-specific configurations. The system also validates user intent, as part of the initial deployment and continuously thereafter, to ensure that the network state does not deviate from the intended state. Any anomaly or deviation can be flagged, and remediation actions can be taken directly from Apstra.

The core benefits of Apstra are:

- Intent-based networking—Apstra automates configuration creation to realize the intent, deploys the configuration to appropriate devices, and continuously validates the operating state against intended state.
- Network Automation—Apstra is a multi-vendor network automation platform that is continuously updated to work with the latest hardware and is extensively tested using modern DevOps practices.
- Recoverability—The Built-in rollback capability of Apstra allows you to quickly restore the system to a known working configuration if needed.
- Day 2+ Management—Apstra's rich data analysis capabilities, including Flow Data, reduce Mean Time to Resolution (MTTR).
- Simplicity—Apstra simplifies network deployment and management. As an example, using Apstra to implement a Data Center Interconnection (DCI), reduces complexity and makes it easy to unify multiple data centers, while isolating failure domains for high availability and resilience.

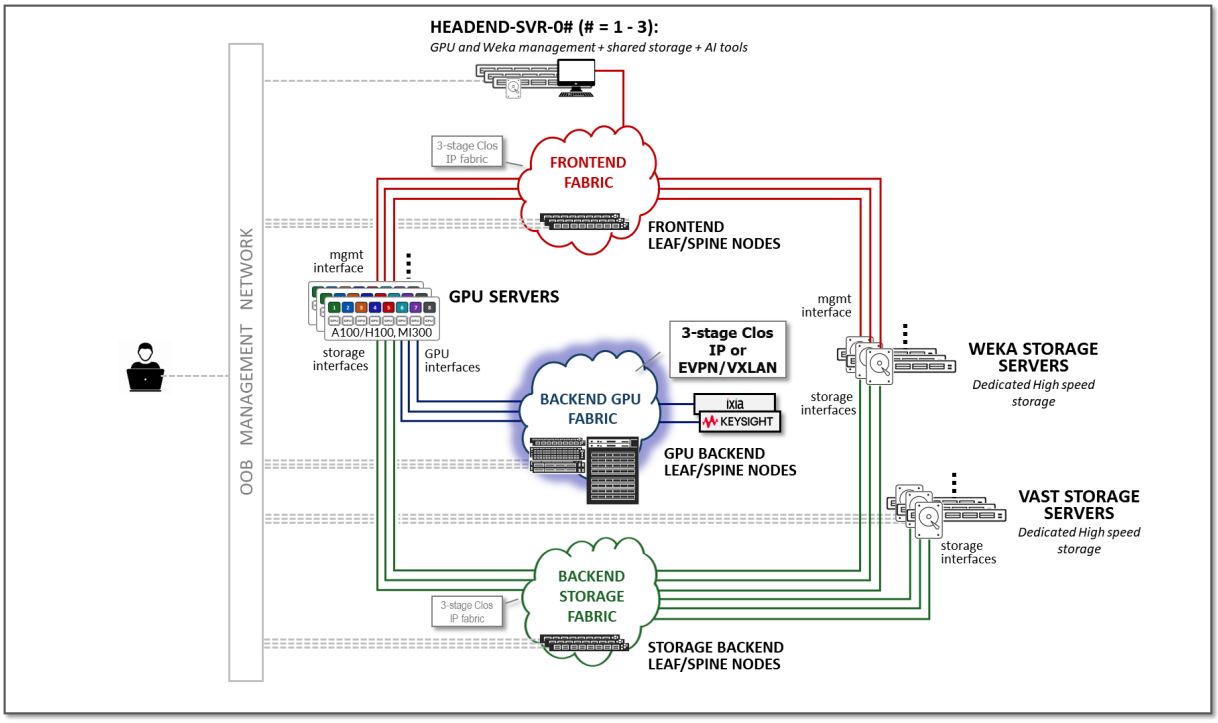
AI Use Case and Reference Design

The **AI JVD Reference Design** covers a complete end-to-end ethernet-based AI infrastructure, which includes the Frontend fabric, GPU Backend fabric and Storage Backend fabric. These three fabrics have a symbiotic relationship, while each provides unique functions to support AI training and inference tasks. The use of Ethernet Networking in AI Fabrics enables our customers to build high-capacity, easy-to-operate network fabrics that deliver the fastest job completion times, maximize GPU utilization, and use limited IT resources.

The AI JVD reference design shown in "Figure 1: AI JVD Reference" on page 5 includes:

- **Frontend Fabric**: This fabric is the gateway network to the GPU nodes and storage nodes from the AI tools residing in the headend servers. The Frontend GPU fabric allows users to interact with the GPU and storage nodes to initiate training or inference workloads and to visualize their progress and results. It also provides an out-of-band path for NCCL (**NVIDIA Collective Communications Library**) collective communication.
- **GPU Backend Fabric**: This fabric connects the GPU nodes (which perform the computations tasks for AI workflows). The GPU Backend fabric transfers high-speed information between GPUs during training jobs, in a lossless manner. Traffic generated by the GPUs is transferred using RoCEv2 (RDMA over Ethernet v2).
- **Storage Backend Fabric**: This fabric connects the high-availability storage systems (which hold the large model training data) and the GPUs (which consume this data during training or inference jobs). The Storage Backend fabric transfers high volumes of data in a seamless and reliable manner.

Figure 1: AI JVD Reference Design



Frontend Overview

The AI Frontend for AI encompasses the interface, tools, and methods that enable users to interact with the AI systems, and the infrastructure that allows for these interactions. The Frontend gives users the ability to initiate training or inference tasks, and to visualize the results, while hiding the underlying technical complexities.

The key components of the Frontend systems include:

- **Model Scheduling**: Tools and methods for managing scripted AI model jobs and commonly based on SLURM (Simple Linux Utility for Resource Management) Workload Manager. These tools enable users to send instructions, commands, and queries, either through a shell CLI or through a graphical web-based interface to orchestrate learning and inference jobs running on the GPUs. Users can configure model parameters, input data, and interpret results as well as initiate or terminate jobs interactively. In the AI JVD, these tools are hosted on the *Headend Servers* connected to the AI Frontend fabric.

- **Management of AI Systems**: Tools for managing (configuring, monitoring and performing maintenance tasks) the AI storage and processing components. These tools facilitate building,

running, training, and utilizing AI models efficiently. Examples include SLURM, TensorFlow, PyTorch, and Scikit-learn.

- **Management of Fabric Components**: Mechanisms and workflows designed to help users effortlessly deploy and manage fabric devices according to their requirements and goals. It includes tasks such as device onboarding, configuration management, and fabric deployment orchestration. This functionality is provided by ***Juniper Apstra*** .
- **Performance Monitoring and Error Analysis**: Telemetry systems tracking key performance metrics related to AI models, such as accuracy, precision, recall, and computational resource utilization (e.g. CPU, GPU usage) which are essential for evaluating model effectiveness during training and inference jobs. These systems also provide insights into error rates and failure patterns during training and inference operations, and help identify issues such as model drift, data quality problems, or algorithmic errors that may affect AI performance. Examples of these systems include Juniper Apstra dashboards, TIG Stack, and Elasticsearch.
- **Data Visualization**: Applications and tools that allow users to visually comprehend insights generated by AI models and workloads. They provide effective visualization that enhances understanding and decision-making based on AI outputs. The same telemetry systems used to monitor and measure System and Network level performance usually provide this visualization as well. Examples of these tools include Juniper Apstra dashboards, TensorFlow, and TIG stack.
- **User Interface**: routing and switching infrastructure that allows communication between the user interface applications and tools and the AI systems executing the jobs, including GPUs and storage devices. This infrastructure ensures seamless interaction between users and the computational resources needed to leverage AI capabilities effectively.
- **GPU-to-GPU control**: communication establishment, information exchange including, QP GIDs (Global IDs), Local and remote buffer addresses, and RDMA keys (RKEYs for memory access permissions)

GPU Backend Overview

The GPU Backend for AI encompasses the devices that execute learning and inference jobs or computational tasks, that is the GPU servers where the data processing occurs, and the infrastructure that allows the GPUs to communicate with each other to complete the jobs.

The key components of the GPU Backend systems include:

AI Systems: Specialized hardware such as GPUs (Graphics Processing Units) and TPUs (Tensor Processing Units) that can execute numerous calculations concurrently. GPUs are particularly adept at handling AI workloads, including complex matrix multiplications and convolutions required to complete learning and

inference tasks. The selection and number of GPU systems significantly impact the speed and efficiency of these tasks.

AI Software: Operating systems, libraries, and frameworks essential for developing and executing AI models. These tools provide the environment necessary for coding, training, and deploying AI algorithms effectively. The functions of these tools include:

Data Management: preprocessing, and transformation of data utilized in training and executing AI models. This encompasses tasks such as cleaning, normalization, and feature extraction. Given the volume and complexity of AI datasets, efficient data management strategies like parallel processing and distributed computing are crucial.

Model Management: tasks related to the AI models themselves, including evaluation (e.g., cross-validation), selection (choosing the optimal model based on performance metrics), and deployment (making the model accessible for real-world applications).

GPU Backend Fabric: routing and switching infrastructure that allows GPU-to-GPU communication for workload distribution, memory sharing, synchronization of model parameters, exchange of results, etc. The design of this fabric can significantly impact the speed and efficiency of AI/ML model training and inference jobs and in most cases shall provide lossless connectivity for GPU-to-GPU traffic.

Storage Backend Overview

The AI storage backend for AI encompasses the hardware and software components for storing, retrieving, and managing the vast amounts of data involved in AI workloads, and the infrastructure that allows the GPUs to communicate with these storage components.

The key aspects of the storage backend include:

High-Performance Storage Devices: optimized for high I/O throughput, which is essential for handling the intensive data processing requirements of the AI tasks such as deep learning. This includes high-performance storage devices designed to facilitate fast access to data during model training and to accommodate the storage needs of large datasets. These storage devices must provide:

Data Management Capabilities: which support efficient data querying, indexing, and retrieval and are crucial for minimizing preprocessing and feature extraction times in AI workflows, as well as for facilitating quick data access during inference.

Scalability: which accommodates growing data volumes and efficiently manages and stores massive amounts of data over time, to support AI workloads often involving large-scale datasets.

Storage Backend Fabric: routing and switching infrastructure that provides connectivity between the GPU and the storage devices. This integration ensures that data can be efficiently transferred between

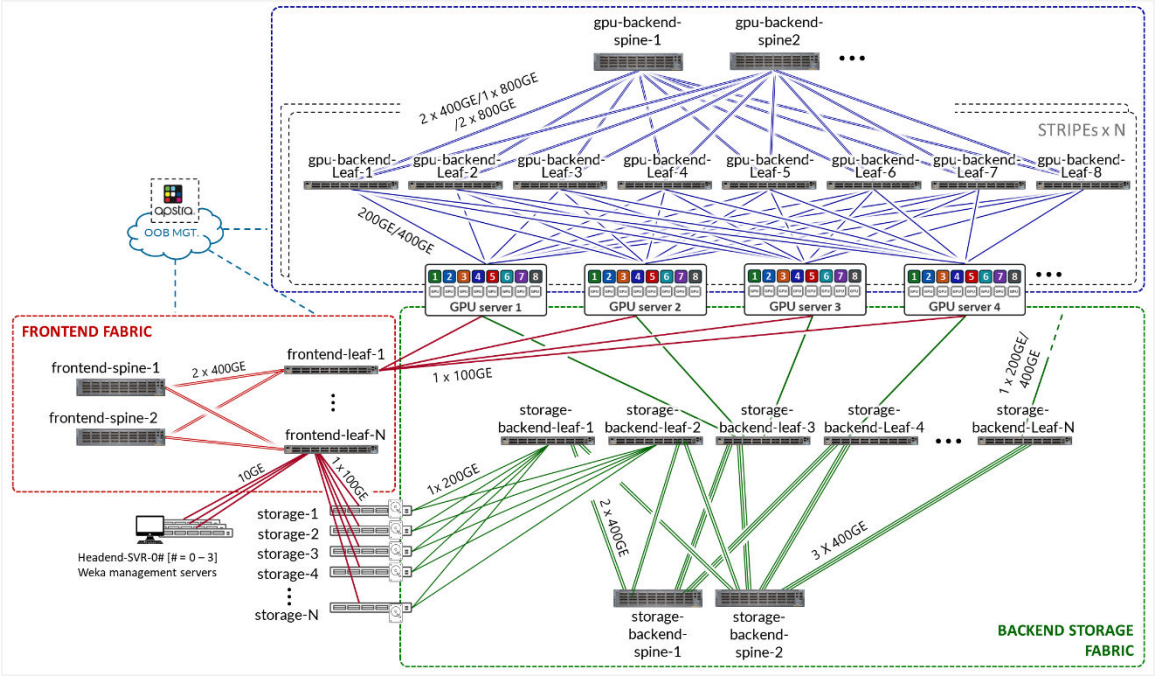
storage and computational resources, optimizing overall AI workflow performance. The performance of the storage backend significantly impacts the efficiency and JCT of AI/ML workflows. A storage backend that provides quick access to data can significantly reduce the amount of time for training AI/ML models.

Solution Architecture

IN THIS SECTION

The three fabrics described in the previous section (Frontend, GPU Backend, and Storage Backend), are interconnected together in the overall AI JVD solution architecture shown in Figure 2.

Figure 2: AI JVD Solution Architecture



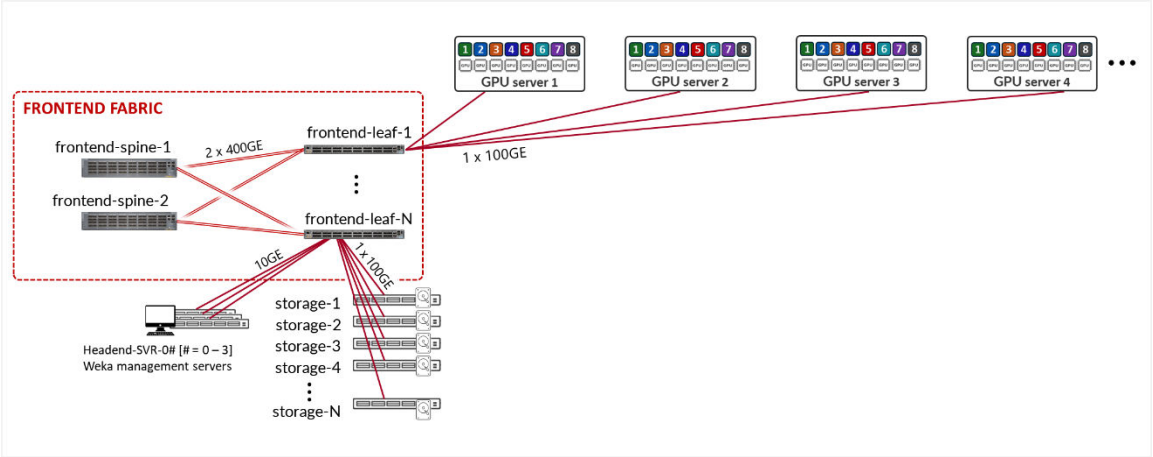
Frontend Fabric

The **Frontend Fabric** provides the infrastructure for users to interact with the AI systems to orchestrate training and inference tasks workflows using tools such as SLURM, Kubernetes, and other AI workflow managers that handle job scheduling, resource allocation, and lifecycle management.

These interactions do not generate heavy data flows and do not impose strict requirements on latency or packet loss. As a result, control-plane traffic does not place rigorous performance demands on the fabric.

The **Frontend Fabric** design consists of a **3-stage L3 IP fabric without high availability (HA)**, as shown in Figure 3. This architecture provides a simple and effective solution for the connectivity required in Frontend. However, any fabric architecture including EVPN/VXLAN, could be used. If an HA-capable Frontend Fabric is required, we recommend following the 3-Stage with Juniper Apstra JVD.

Figure 3: Frontend Fabric Architecture



The number of leaf nodes is dependent on the number of servers and storage devices in the AI cluster, as well as any other device used for AI job scheduling, resource allocation, and lifecycle management.

The number of spine nodes is dependent on the subscription factor desired for the design. A 1:1 subscription factor is not required. Moderate oversubscription is acceptable for control-plane traffic, provided the design maintains resiliency and avoids congestion that would impact control-plane stability.

The fabric is an L3 IP fabric using EBGP for route advertisement with IP addressing and EBGP configuration details described in the networking section on this document. No special load balancing mechanism is required. ECMP across redundant L3 paths is typically sufficient.

Given that the control-plane traffic is typically not bandwidth-heavy compared to storage or GPU fabrics, strict QoS mechanisms are optional and only recommended if sharing links with bursty non-control traffic.

The devices and connectivity in the Frontend fabric validated in this JVD are summarized in the following tables:

Table 1: Validated management devices and GPU servers connected to the Frontend fabric

GPU Servers	Storage Devices	Headend Servers
• NVIDIA DGX H100 w/ NVIDIA H100 80GB HBM3 GPUs • Supermicro AS-4124GO-NART+ NVIDIA A100-SXM4 80GB GPUs	Weka CSE-LB16TS-R860AWP-A	Supermicro SYS-6019U-TR4

Table 2: Validated Frontend Fabric leaf and spine nodes

Frontend Fabric Leaf Nodes switch model	Frontend Fabric Spine Nodes switch model
QFX5130-32CD	QFX5130-32CD
QFX5220-32CD	QFX5220-32CD

Table 3: Validated connections between headend servers and leaf nodes in the Frontend Fabric

Links per GPU server to leaf connection	Server Type
1 x 10GE	Supermicro SYS-6019U-TR4

Table 4: Validated connections between GPU servers and leaf nodes in the Frontend

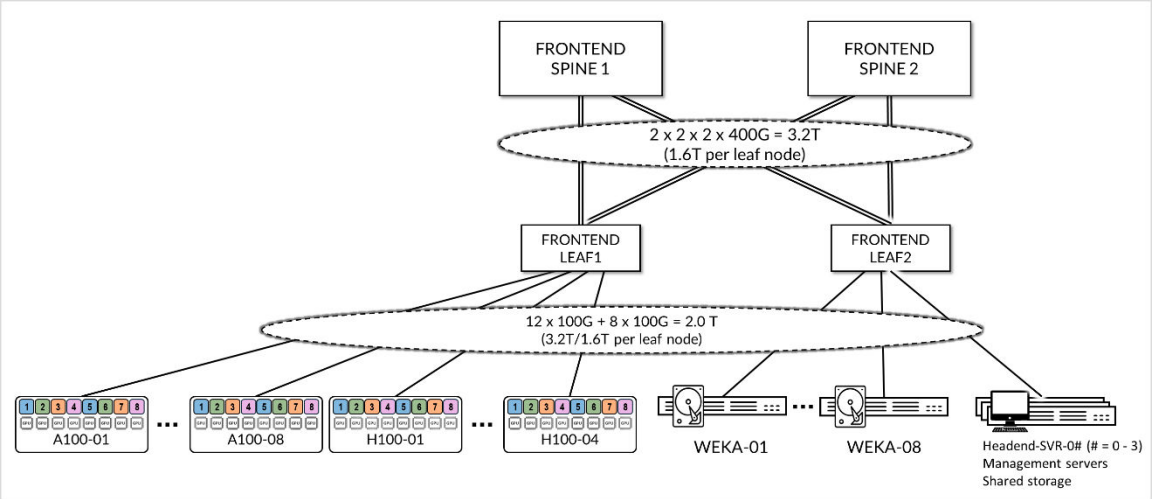
Links per GPU server to leaf connection	Server Type
1 x 100GE	NVIDIA A100
1 x 100GE	NVIDIA H100

Table 5: Validated connections between leaf and spine nodes in the Frontend

Links per leaf and spine connection	Leaf node model	spine node model
2 x 400GE	QFX5130-32CD	QFX5130-32CD

Testing for this JVD was performed using 8 NVIDIA A100 GPU servers and 4 NVIDIA H100 GPU servers connected to two leaf nodes, which in turn were connected to two spine nodes, as shown:

Figure 4: Frontend Fabric JVD Testing Topology



- GPU servers are connected to the Leaf nodes using 100G interfaces (ConnectX-6/ConnectX-7 NICs).
- Weka devices are connected to the Leaf nodes using 100G interfaces

Table 6: Aggregate Frontend GPU Servers <=> Frontend Leaf Nodes Link Counts and bandwidth tested

GPU Servers <=> Frontend Leaf Nodes	**Bandwidth**
Number of 100GE links GPU servers ó frontend leaf nodes = 12 (1 per server)	12 x 100GE = 1.2 Tbps
Number of 100GE links between Storage device ó frontend leaf nodes = 8 (1 per storage device)	8 x 100GE = 0.8 Tbps
Total bandwidth =	**2.0 Tbps**

Table 7: Aggregate Frontend Leaf Nodes <=> Frontend Spine Nodes Link Counts and bandwidth tested

Frontend Leaf Nodes <=> Frontend Spine Nodes	**Bandwidth**
Number of 400GE links between frontend leaf nodes and spine nodes = 8 (2 leaf nodes x 2 spines nodes x 2 links per leaf to spine connection)	8 x 400GE = 3.2 Tbps
Total bandwidth =	**3.2 Tbps**

Frontend Leaf Nodes <=> Frontend Spine Nodes	Bandwidth
No over subscription.	

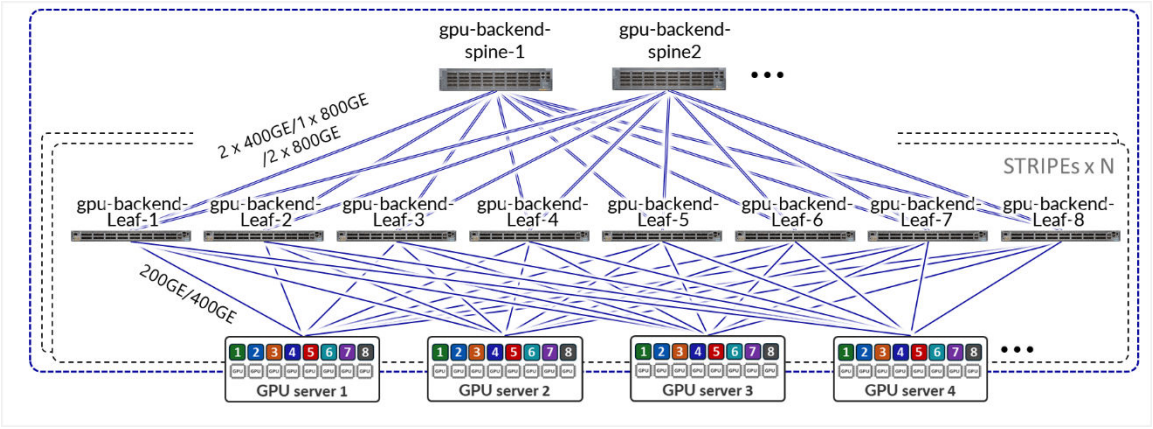
GPU Backend Fabric

The **GPU Backend fabric** provides the infrastructure for GPUs to communicate with each other within a cluster, using RDMA over Converged Ethernet (RoCEv2). ROCEv2 boosts data center efficiency, reduces overall complexity, and increases data delivery performance by enabling the GPUs to communicate as they would with the InfiniBand protocol.

Unlike the Frontend Fabric, the GPU Backend Fabric carries **data-plane traffic that is both bandwidth-intensive and latency-sensitive**. Packet loss, excessive latency, or jitter can significantly impact job completion times and therefore must be avoided. As a result, one of the primary design objectives of the GPU Backend Fabric is to provide a **near-lossless Ethernet fabric**, while also delivering **maximum throughput, minimal latency, and minimal network interference** for GPU-to-GPU traffic. RoCEv2 operates most efficiently in environments where packet loss is minimized, directly contributing to optimal job completion times.

The **GPU Backend Fabric** in this JVD was designed to meet these requirements. The design follows a **3-stage IP Clos,** " Rail Optimized Stripe architecture " on page 20, as shown in Figure 5. Details about the "Backend GPU Rail Optimized Stripe Architecture" on page 22 are described in a later section.

Figure 5: GPU Backend Fabric Architecture



The fabric operates as an L3 IP fabric using EBGP for route advertisement with IP addressing and EBGP configuration details described in the networking section on this document.

In a rail optimized architecture, the number of **leaf nodes** is determined by the number of GPU per server, which is 8 for the Nvidia servers included in this JVD. The number of **spine nodes** as well as the speed and number of links between GPU servers and leaf nodes, and between leaf and spine nodes, determines the **effective bandwidth** and **oversubscription characteristics** of the GPU Backend Fabric.

In contrast to the **Frontend Fabric**, the **GPU Backend Fabric** requires a **non-oversubscribed design** (**1:1 subscription factor**) to ensure sufficient bandwidth for the high volume RoCEv2 traffic, and prevent congestion, packet loss and excessive latency.

Traffic distribution within the GPU Backend Fabric relies on **ECMP** across multiple equal-cost L3 paths combined with advanced Load Balancing techniques such as **Dynamic Load Balancing (DLB)**, **Global Load Balancing**, and **Adaptive Load Balancing (ALB)**. These are described in the **Load Balancing section** of this document.

Because the **GPU Backend Fabric** carries RoCEv2 traffic sensitive to losses and latency, the design incorporates DCQCN (Data Center Quantized Congestion Notification), which leverages ECN (Explicit Congestion Notification) and may optionally use PFC (Priority Flow Control), to achieve lossless or near-lossless behavior for RDMA traffic. These mechanisms are described in detail in the **Class of Service section** of this document.

The devices and connectivity in the GPU backend fabric validated in this JVD are summarized in the following tables:

Table 8: Validated management devices and GPU servers connected to the GPU Backend Fabric.

GPU Servers	Storage Devices	Headend Servers
• NVIDIA DGX H100 • w/ NVIDIA H100 80GB HBM3 GPUs • Supermicro AS -4124GO-NART+ NVIDIA A100-SXM4 80GB GPUs	Weka CSE-LB16TS-R860AWP-A	Supermicro SYS-6019U-TR4

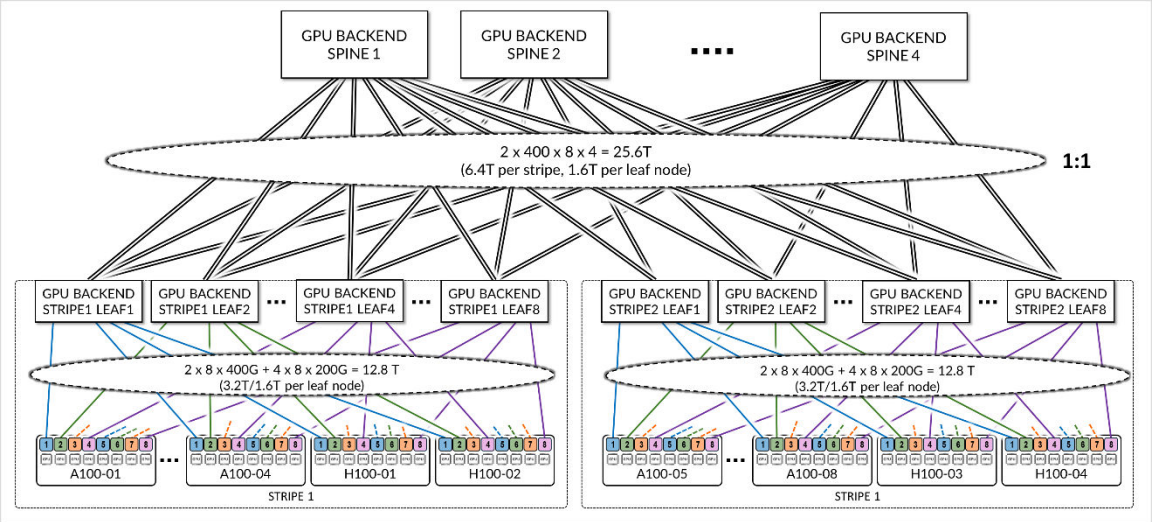
Testing for this JVD was performed using 8 NVIDIA A100 GPU servers and 4 NVIDIA H100 GPU servers connected to two stripes as shown:

Figure 6: GPU Backend Fabric JVD Testing Topology



- Each Nvidia A100 server is connected to the Leaf nodes using 200G interfaces (ConnectX-7 NICs).
- Each Nvidia H100 server is connected to the Leaf nodes using 400G interfaces (ConnectX-7 NICs).

Table 13: Per stripe Server to Leaf Bandwidth

Stripe	Number of servers per Stripe	Number of servers <=> leaf links per server (same as number of leaf nodes & number of GPUs per server)	Server <=> Leaf Link Bandwidth [Gbps]	Total Servers <=> Leaf Links Bandwidth per stripe [Tbps]
1	2 H100	8	400 Gbps	2 x 8 x 400 Gbps = 6.4 Tbps
	4 A100	8	200 Gbps	4 x 8 x 200 Gbps = 6.4 Tbps
2	2 H100	8	400 Gbps	2 x 8 x 400 Gbps = 6.4 Tbps
	4 A100	8	200 Gbps	4 x 8 x 200 Gbps = 6.4 Tbps
Total Server <=> Leaf Bandwidth				**25.6 Tbps**

Table 14: Per stripe Leaf to Spine Bandwidth w/ QFX5240 as leaf and spines

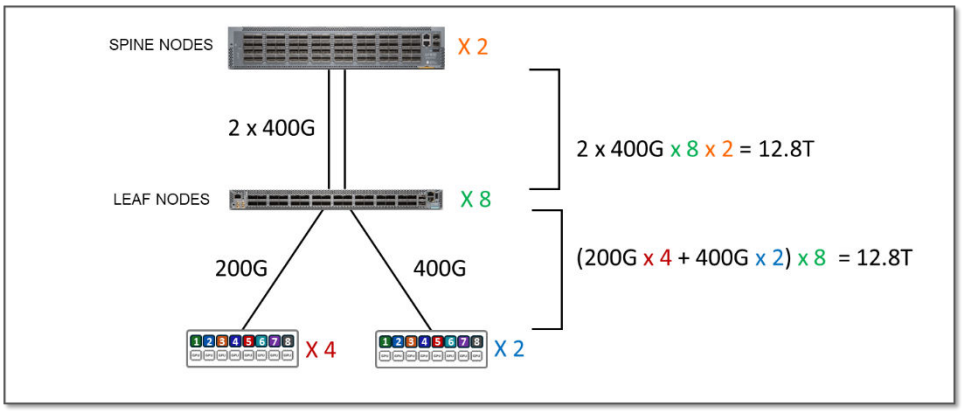
Stripe	Number of leaf nodes	Number of spine nodes	Number of 400 Gbps leaf <=> spine links per leaf node	Server <=> Leaf Link Bandwidth [Gbps]	Bandwidth Leaf <=> Spine Per Stripe [Tbps]
1	8	4	2	400	8 x 2 x 2 x 400 Gbps = 12.8 Tbps
2	8	4	2	400	8 x 2 x 2 x 400 Gbps = 12.8 Tbps
Total Server <=> Leaf Bandwidth					**25.6 Tbps**

GPU Backend Fabric Subscription Factor

The subscription factor is simply calculated by comparing the numbers from the two tables above:

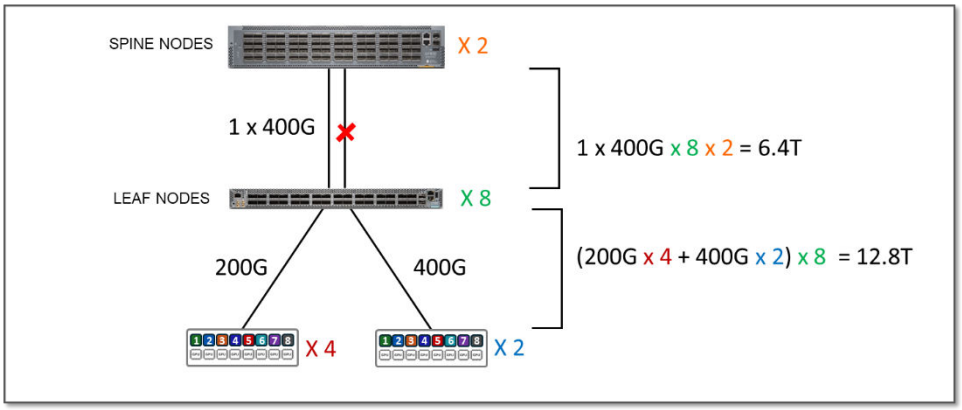
In the JVD test environment, the bandwidth between the servers and the leaf nodes is 25.6 Tbps per stripe, while the bandwidth available between the leaf and spine nodes is 25.6 Tbps per stripe. This means that the fabric has enough capacity to process all traffic between the GPUs even when this traffic was 100% inter-stripe, but now there is no extra capacity to accommodate additional servers. The subscription factor in this case is 1:1 (no subscription).

Figure 7: 1:1 Subscription Factor



To run oversubscription testing, some of the interfaces between the leaf and spines were disabled, reducing the available bandwidth, as shown in the example in Figure 8:

Figure 8: 2:1 Subscription Factor (Oversubscription)



The total Servers to Leaf Links bandwidth per stripe has not changed. It is still 12.8 Tbps as shown in table 15 in the previous scenario.

However, the bandwidth available between the leaf and spine nodes is now only 6.4 Tbps per stripe.

Table 15: Per Stripe Leaf to Spine Bandwidth

Leaf to Spine Bandwidth per Stripe

Leaf <=> Spine Links Per Spine Node & Per Stripe	Speed Of Leaf <=> Spine Links [Gbps]	Number of Spine Nodes	Total Bandwidth Leaf <=> Spine Per Stripe [Tbps]
8	1 x 400	2	6.4

This means that the fabric no longer has enough capacity to process all traffic between the GPUs even if this traffic was 100% inter-stripe, potentially causing congestion and traffic loss. The oversubscription factor in this case is 2:1.

Congestion and failure testing results are included in the JVD Test Report.

GPU to GPU Communication Optimization

Optimization in rail-optimized topologies refers to how GPU communication is managed to minimize congestion and latency while maximizing throughput. A key part of this optimization strategy is keeping traffic local whenever possible. By ensuring that GPU communication remains within the same rail or stripe, or even within the server, the need to traverse spines or external links is reduced, which lowers latency, minimizes congestion, and enhances overall efficiency.

While localizing traffic is prioritized, inter-stripe communication will be necessary in larger GPU clusters. Inter-stripe communication is optimized by means of proper routing and balancing techniques over the available links to avoid bottlenecks and packet loss.

The essence of optimization lies in leveraging the topology to direct traffic along the shortest and least-congested paths, ensuring consistent performance even as the network scales. Traffic between GPUs on the same servers can be forwarded locally across the internal Server fabric (vendor dependent), while traffic between GPUs on different servers happens across the external GPU backend infrastructure. Communication between GPUs on different servers can be intra-rail, or inter-rail/inter-stripe.

Intra-rail traffic is switched (processed at Layer 2) on the local leaf node. Following this design, data between GPUs on different servers (but in the same stripe) is always moved on the same rail and across one single switch. This guarantees GPUs are 1 hop away from each other and will create separate independent high-bandwidth channels, which minimize contention and maximize performance. On the other hand, inter-rail/inter-stripe traffic is routed across the IRB interfaces on the leaf nodes and the spine nodes connecting the leaf nodes (processed at Layer 3).

Consider the example depicted in Figure 8

- Communication between GPU 1 and GPU 2 in server 1 happens across the server's internal fabric (1)
- Communication between GPUs 1 in servers 1- 4, and between GPUs 8 in servers 1- 4 happens across Leaf 1 and Leaf 8 respectively (2), and
- Communication between GPU 1 and GPU 8 (in servers 1- 4) happens across leaf1, the spine nodes, and leaf8 (3)

Figure 8: Inter-rail vs. Intra-rail GPU-GPU communication

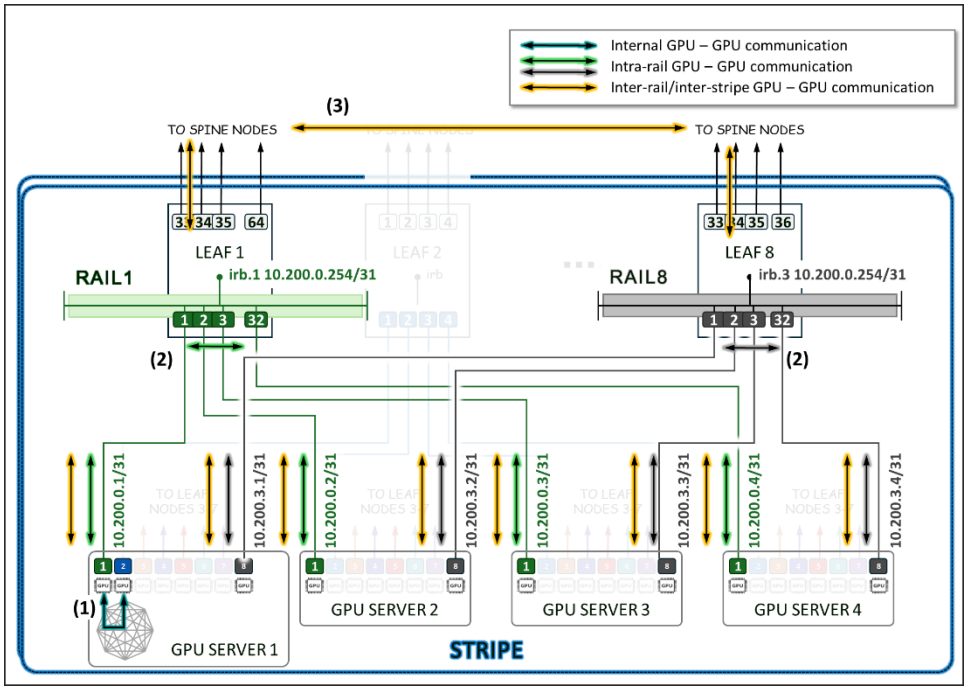


Figure 10 represents a topology with one **stripe** and 8 **rails** connecting GPUs 1-8 across leaf switches 1-8 respectively.

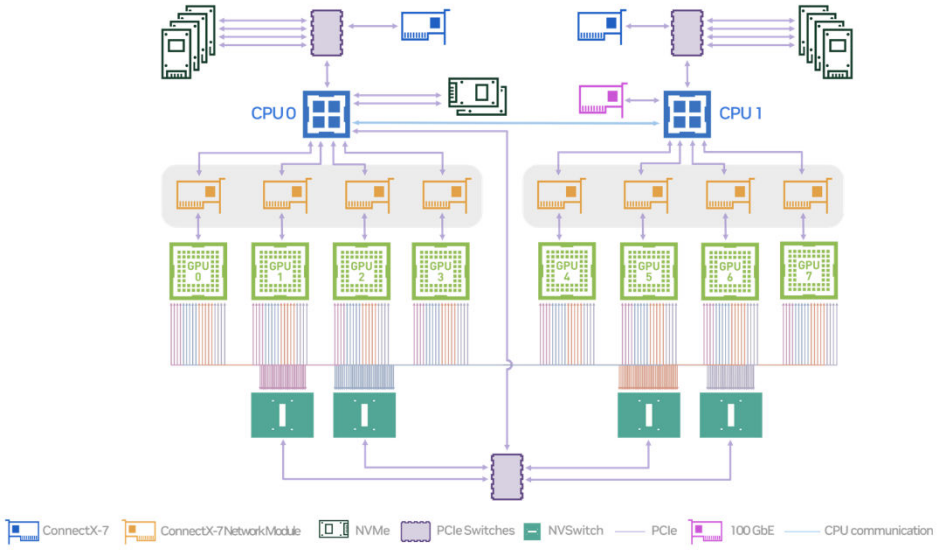
Communication between GPU 7 and GPU 8 in Server 1 happens across the internal fabric, while communication between GPU 1 in Server 1 and GPU 1 in Server N1 happens across Leaf switch 1 (within the same rail).

Notice that if any communication between GPUs in different stripes and different servers is required (e.g. GPU 4 in server 1 communicating with GPU 5 in Server N1), data is first moved to a GPU interface in the same rail as the destination GPU, thus sending data to the destination GPU without crossing rails.

Following this design, data between GPUs on different servers (but in the same stripe) is always moved on the same rail and across one single switch, which guarantees GPUs are 1 hop away from each other and creates separate independent high-bandwidth channels, which minimize contention and maximize performance.

On NVIDIA H100s GPU servers, GPUs are interconnected via **NVLink and NVswitches**, which provide 400Gbps GPU-to-GPU high-bandwidth, low-latency, bidirectional GPU-to-GPU communication within a single server, as shown in Figure 9.

Figure 9: NVIDIA HGX/DGX GPU interconnect architecture



For more details refer to Introduction to NVIDIA DGX H100/H200 Systems — NVIDIA DGX H100/H200 User Guide

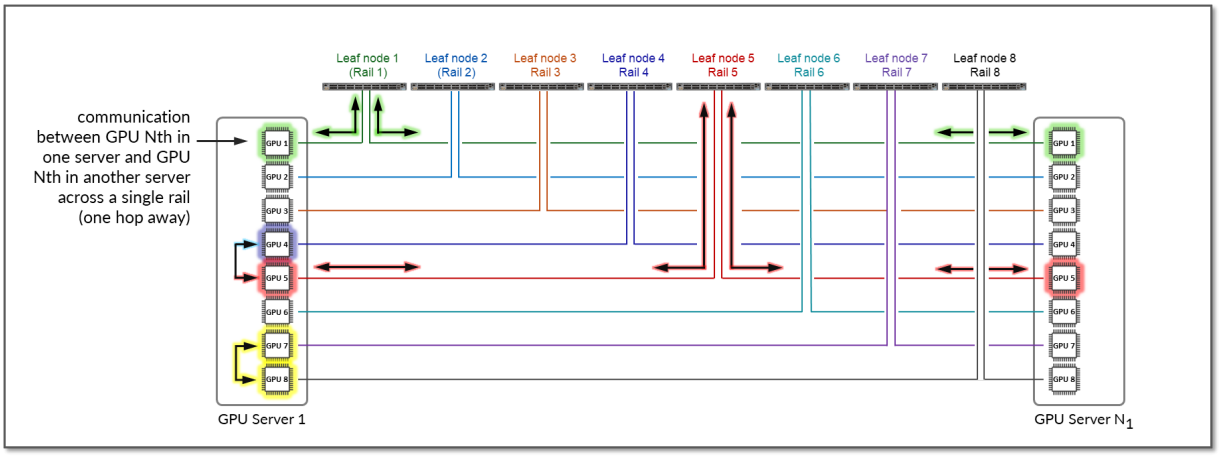
NVIDIA GPUs leverage **NVLink and NVSwitch** to deliver high-bandwidth, low-latency communication between GPUs, CPUs, and other system components. This interconnect fabric dynamically manages traffic across multiple links, providing optimized paths for intra-node GPU communication and enabling efficient collective operations.

By default, NVIDIA GPU platforms implement **topology-aware routing and local optimization, implemented using PXN (Parallel Execution Networks),** to minimize latency for GPU-to-GPU traffic. Communication between GPUs on the same servers is forwarded across the Infinity Fabric and remains **intra-node** and does not traverse the external Ethernet fabric. Traffic between GPUs of the same rank across multiple servers remains **intra-stripe**.

Figure 12 shows an example where GPU1 in Server 1 communicates with GPU1 in Server 2. The traffic is forwarded by Leaf Node 1 and remains within Rail 1.

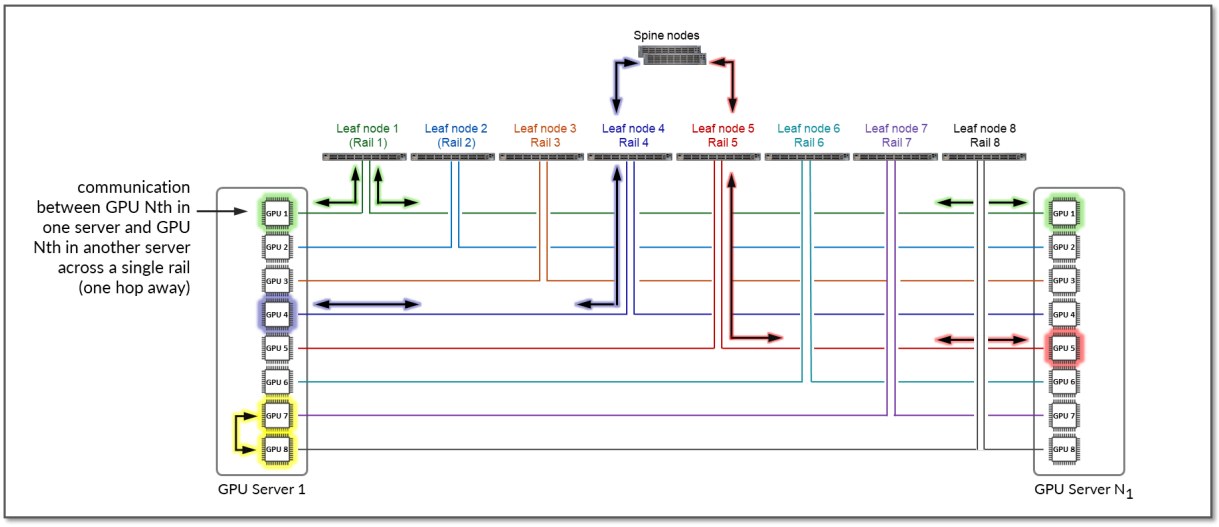
Additionally, if GPU4 in Server 1 wants to communicate with GPU5 in Server 2, and GPU5 in Server 1 is available as a local hop in AMD's Infinity Fabric, the traffic naturally prefers this path to optimize performance and keep GPU-to-GPU communication intra-rail.

Figure 10: GPU to GPU inter-rail communication between two servers **with local optimization**.



If local optimization is not feasible because of workload constraints, for example, the traffic must bypass local hops (internal fabric) and use RDMA (off-node NIC-based communication). In such a case, GPU4 in Server 1 communicates with GPU5 in Server 2 by sending data directly over the NIC using RDMA, which is then forwarded across the fabric, as shown in Figure 11.

Figure 11: GPU to GPU inter-rail communication between two servers **without local optimization**.



The example shows that communication between GPU 4 in Server 1 and GPU 5 in Server N1 goes across Leaf switch 1, the Spine nodes, and Leaf switch 5 (between two different rails).

Backend GPU Rail Optimized Stripe Architecture

As previously described, a **Rail Optimized Stripe Architecture** provides efficient data transfer between GPUs, especially during computationally intensive tasks such as AI Large Language Models (LLM) training workloads, where seamless data transfer is necessary to complete the tasks within a reasonable

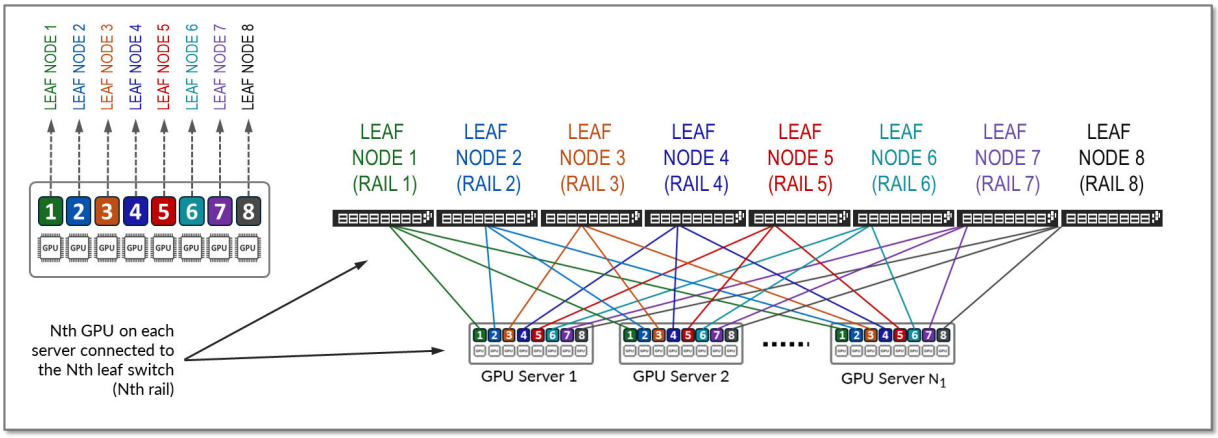
timeframe. A Rail Optimized topology aims to maximize performance by providing minimal bandwidth contention, minimal latency, and minimal network interference, ensuring that data can be transmitted efficiently and reliably across the network.

In a Rail Optimized Stripe Architecture, there are two important concepts: **rail** and **stripe**.

The GPUs on a server are numbered 1-8, where the number represents the GPU's position in the server, as shown in Figure 6. This number is sometimes called **rank** or more specifically "**local rank**" in relationship to the GPUs in the server where the GPU sits, or "**global rank**" in relationship to all the GPUs (in multiple servers) assigned to a single job.

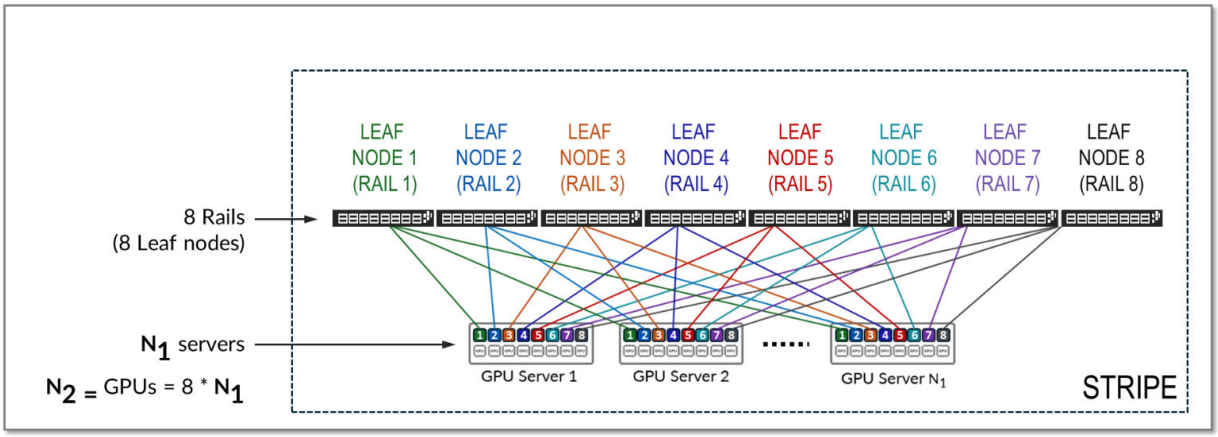
A **rail** connects GPUs of the same order across one of the leaf nodes in the fabric; that is, rail Nth connects all GPUs in position Nth on all the servers, to leaf node Nth, as shown in Figure 10.

Figure 10: Rails in a Rail Optimized Architecture



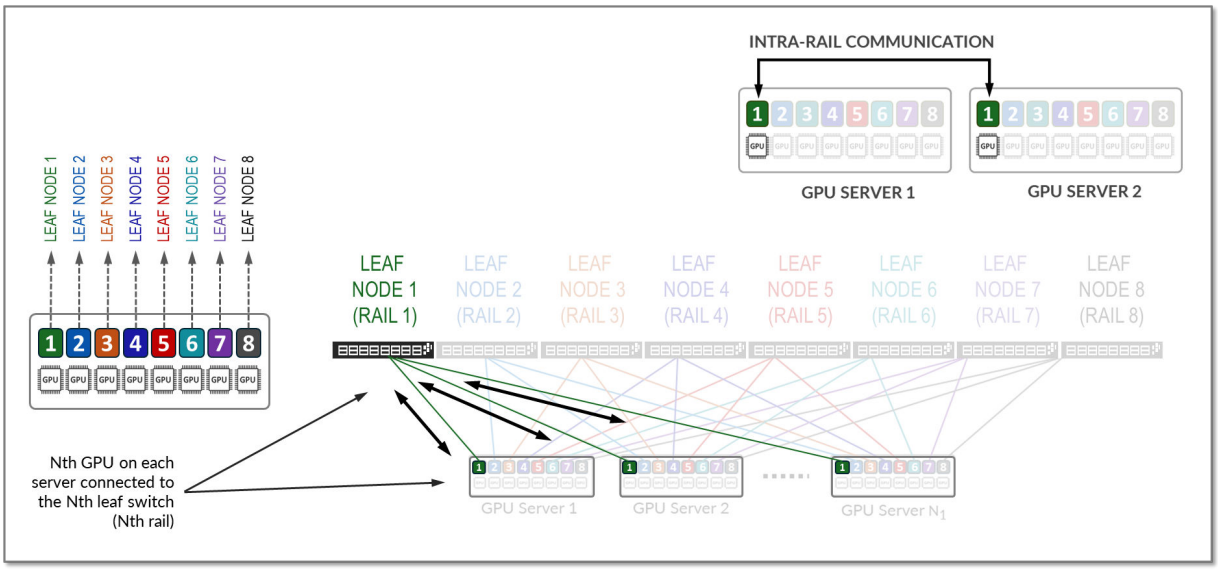
A **stripe** refers to a design module or building block, comprised of multiple **rails**, and that includes a number of Leaf nodes and GPU servers, as shown in Figure 11. This building block can be replicated to scale up the AI cluster.

Figure 11: Stripes in a Rail Optimized Architecture



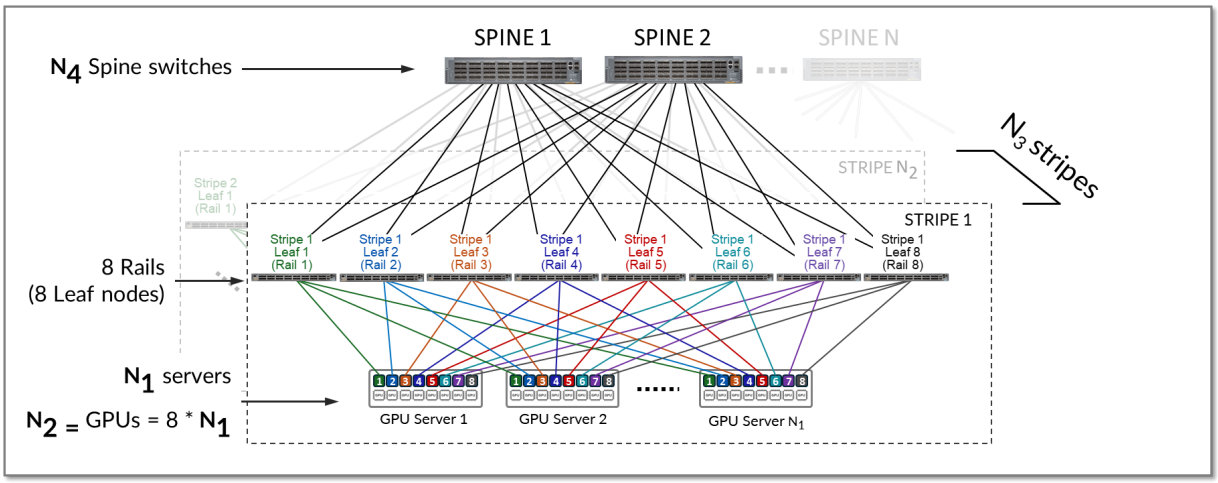
All traffic between GPUs of the same rank (intra-rail traffic) is forwarded at the leaf node level as shown in Figure 12.

Figure 12: Intra-rail GPU to GPU traffic example.



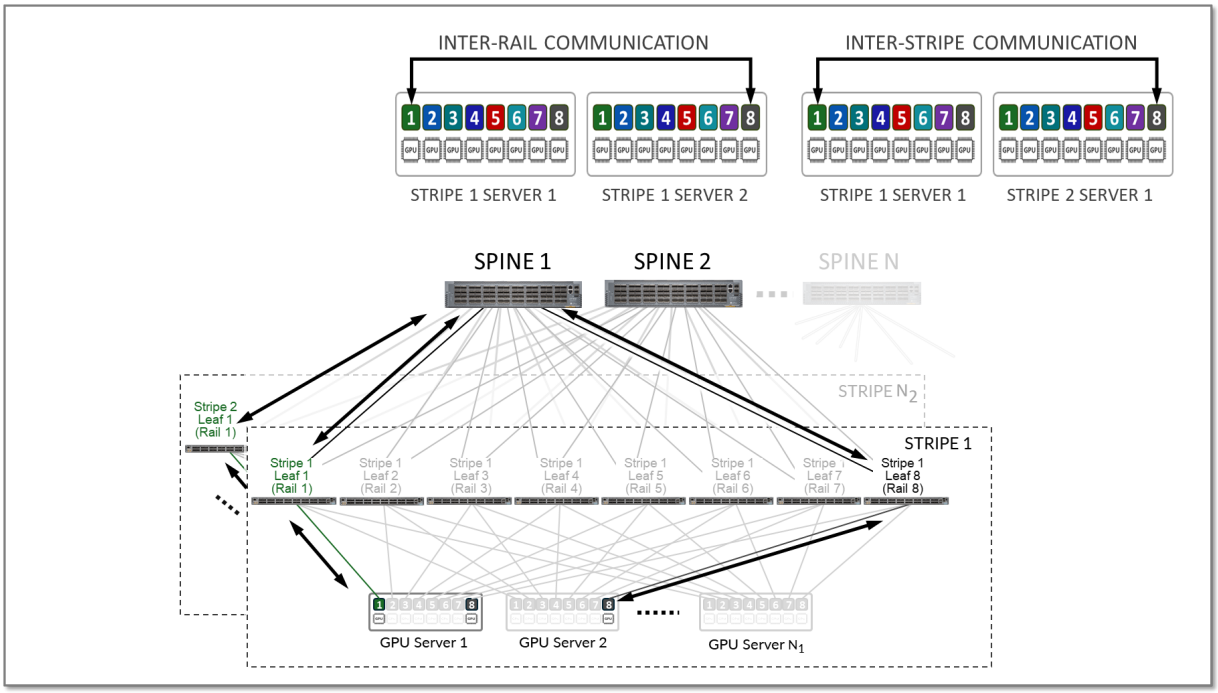
A stripe can be replicated to scale up the number of servers (N_1) and GPUs (N_2) in an AI cluster. Multiple stripes (N_3) are then connected across Spine switches as shown in Figure 13.

Figure 13: Multiple stripes connected via Spine nodes



Both **Inter-rail** and **inter-stripe** traffic will be forwarded across the spines nodes as shown in figure 14.

Figure 14. Inter-rail, and Inter-stripe GPU to GPU traffic example.



Calculating the number of leaf and spine nodes, Servers, and GPUs in a rail optimized architecture

The **number of leaf nodes** in a single stripe in a rail optimized architecture is defined by the number of GPUs per server (number of rails). Each NVIDIA DGX H100 GPU server includes 8 NVIDIA H100 Tensor core GPUs. Therefore, a single stripe includes 8 leaf nodes (8 rails).

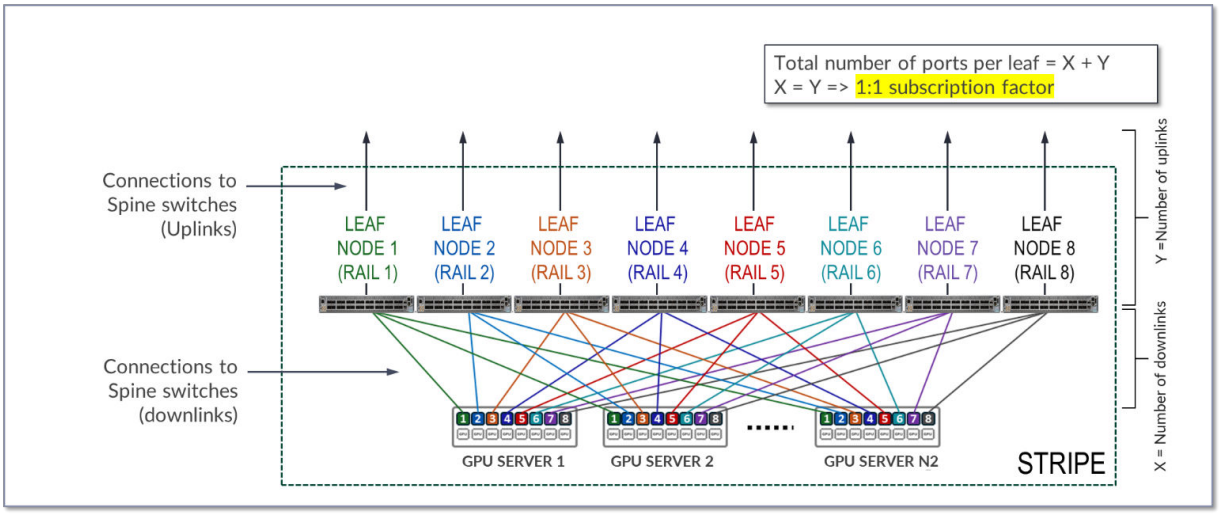
Number of leaf nodes = number of GPUs per server = 8

The **maximum number of servers** supported in a single stripe (N1) is defined by the **number of available ports** on the Leaf node which depends on the switches model.

The total bandwidth between the GPU servers and leaf nodes must match the total bandwidth between leaf and spine nodes to maintain a 1:1 subscription ratio.

Assuming all the interfaces on the leaf node operate at the same speed, half of the interfaces will be used to connect to the GPU servers, and the other half to connect to the spines. Thus, the **maximum number of servers** in a stripe is calculated as half the **number of available ports** on each leaf node.

Figure 15. Number of uplinks and downlinks for 1:1 subscription factor



In the diagram, X represents the number of downlinks (links between leaf nodes and the GPU servers), while Y represents the number of uplinks (links between the leaf nodes and the spine nodes). To allow for a 1:1 subscription factor, X must be equal to Y.

The **number of available ports** on each leaf node is equal to X + Y or 2 * X.

Because all servers in a stripe have one port connected to every leaf in the stripe, the maximum number of servers in the stripe (N_1) is equal X.

N_1 (maximum number of servers per stripe) = number of available ports ÷ 2

The **maximum number of GPUs** in the stripe is calculated by simply multiplying the number of GPUs per server.

N2 (maximum number of GPUs) = N1 (maximum number of servers per stripe) * 8

The **total number of available ports** is dependent on the switch model used for the leaf node. Table 16 shows some examples.

Table 16: Maximum number of GPUs supported per stripe

Leaf Node QFX switch Model	total number of available 400 GE ports per switch	Maximum number of servers supported per stripe for 1:1 Subscription (N_1)	GPUs per server	Maximum number of GPUs supported per stripe (N_2)
QFX5220-32CD	32	32 ÷ 2 = 16	8	16 servers x 8 GPUs/ server = 128 GPUs

(Continued)

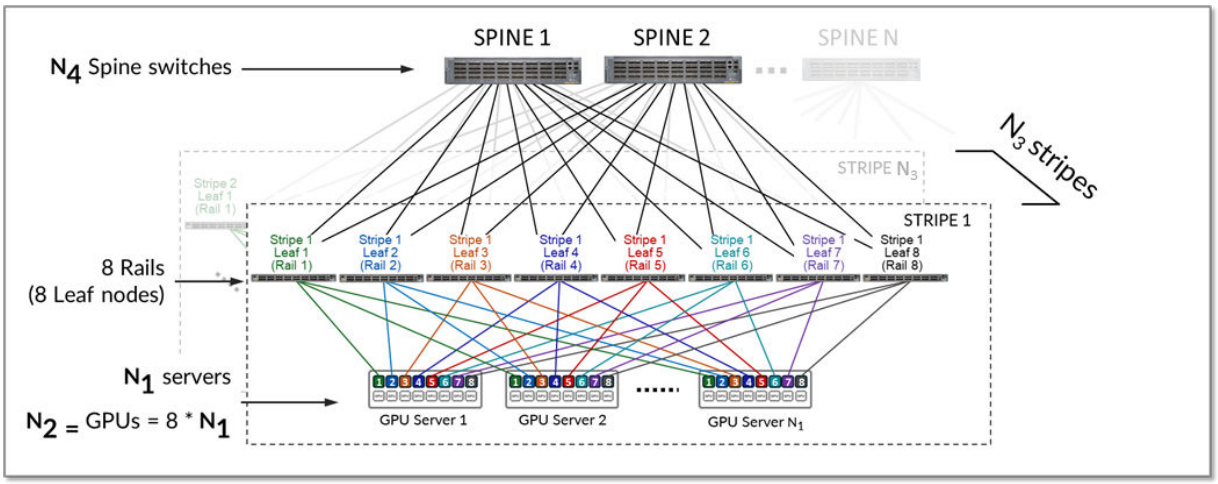
Leaf Node QFX switch Model	total number of available 400 GE ports per switch	Maximum number of servers supported per stripe for 1:1 Subscription (N_1)	GPUs per server	Maximum number of GPUs supported per stripe (N_2)
QFX5230-64CD	64	64 ÷ 2 = 32	8	32 servers x 8 GPUs/ server = 256 GPUs
QFX5240-64OD QFX5241-64OD	128	128 ÷ 2 = 64	8	64 servers x 8 GPUs/ server = 512 GPUs

- QFX5220-32CD switches provide 32 x 400 GE ports (16 will be used to connect to the servers and 16 will be used to connect to the spine nodes)
- QFX5230-64CD switches provide up to 64 x 400 GE ports (32 will be used to connect to the servers, and 32 will be used to connect to the spine nodes).
- QFX5240-64OD switches provide up to 128 x 400 GE ports (64 will be used to connect to the servers, and 64 will be used to connect to the spine nodes).

NOTE: QFX5240-64OD switches come with 64 x 800GE ports which can break out into 2x400GE ports, for a maximum of 128 400GE interfaces shown in table 16.

To achieve larger scales, multiple stripes (N_3) can be connected using a set of Spine nodes (N_4), as shown in Figure 10.

Figure 16: Multiple Stripes connected across Spine nodes.



The **number of stripes required** (N_3) is calculated based on the **required number of GPUs**, and the **maximum number of GPUs per stripe (N_2)**.

For example, assume that the required number of GPUs (GPUs) is 16,000, and the fabric is using QFX5240-64OD as leaf nodes.

The number of available 400G ports is 128, which means that:

- the maximum number of servers per stripe (N_1) = 64
- the maximum number of GPUs per stripe (N_2) = 512

The **number of stripes** (N_3) required is calculated by dividing the number of GPUs required, and the number of GPUs per stripe as shown:

N_3 (number of stripes) = GPUs ÷ N_2 (maximum number of GPUs per stripe) = 16000 ÷ 512 = 32 stripes (rounded up)

With 32 stripes & 64 servers per stripe, the cluster can provide 16,384 GPUs.

Knowing the **number of stripes required** (N_3) and the **number of uplinks ports per leaf node** (Y) you can calculate how many spine nodes are required.

Remember X = Y = N1

First the **total number of leaf nodes** can be calculated by multiplying the **number of stripes required** by 8 (number of leaf nodes per stripe).

Total number of leaf nodes = N_3 x 8 = 32 x 8 = 256

Then the **total number of uplinks** can be obtained multiplying the number of uplinks per leaf node (N_1), and the total number of leaf nodes.

Total number of uplinks = N_1 x 256 = 64 x 256 = 16384

The **number of spines required** (N_4) can then be determined by dividing the **total number of uplinks** by the **number of available ports on each spine node**, which as for the leaf nodes, depends on the switch model used for the spine role.

Number of spines required (N_4) = **16384 / number of available ports on each spine node**

For example, if the spine nodes are **QFX5240/41**, the number of available ports on each spine node **is 128**.

Table 17: Number of spines nodes for two stripes.

Spine Node QFX switch Model	Maximum number of 400 GE interfaces per switch	Number of spines required (N_4) with 64 stripes
QFX5240-64OD	128	**32768** ÷ 128 = 128
PTX10008 LC1201	288	**32768** ÷ 288 ~ 57
PTX10008 LC1301	576	**32768** ÷ 576 ~ 29

Storage Backend Fabric

The **Storage Backend fabric** provides the connectivity infrastructure for storage devices to be accessible from the GPU servers.

The performance of the storage infrastructure significantly impacts the efficiency of AI workflows. A storage system that provides quick access to data can significantly reduce the amount of time for training AI models. Similarly, a storage system that supports efficient data querying and indexing can minimize the completion time of preprocessing and feature extraction in an AI workflow.

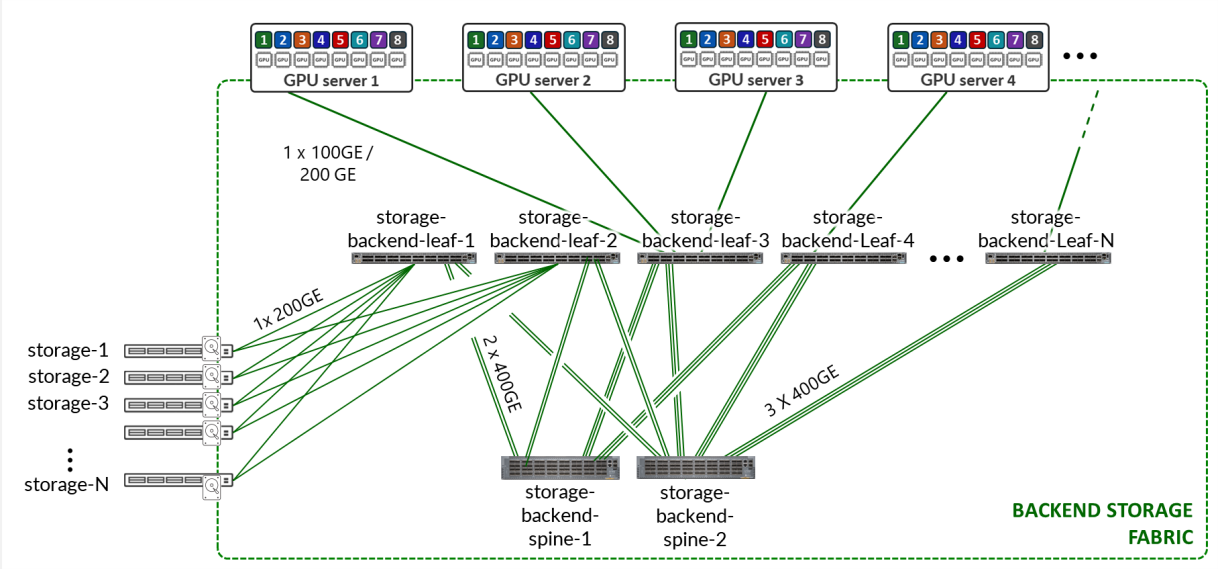
In small clusters, it may be sufficient to use the local storage on each GPU server, or to aggregate this storage together using open-source or commercial software. In larger clusters with heavier workloads, an external dedicated storage system is required to provide dataset staging for ingest, and for cluster checkpointing during training.

Two leading platforms, WEKA and Vast Storage, provide cutting-edge solutions for shared storage in GPU environments. While we have tested both solutions in our lab, **this JVD focuses on the Weka Storage Solution**. Thus, the rest of this, as well as other sections in this document, will cover details about **Weka Storage devices** and connectivity to the Storage Backend Fabric.

Details about the **Vast storage** are included in the *AI Data Center Network with Juniper Apstra, AMD GPUs, Broadcom NIC, AMD Pollara NIC, and Vast Storage—Juniper Validated Design (JVD).*

The **Storage Backend fabric** design in the JVD also follows a 3-stage IP clos architecture as shown in Figure 17. There is no concept of rail-optimization in a storage cluster. Each GPU server has a single connection to the leaf nodes, instead of one per GPU.

Figure 17: Storage Backend Fabric Architecture



The number of leaf nodes depends on the GPU number of servers and storage devices in the AI cluster.

The number of spine nodes is dependent on the subscription factor desired for the design. Like the **GPU Backend Fabric,** the **Storage Fabric** requires a **non-oversubscribed design** (**1:1 subscription factor**) to ensure sufficient bandwidth for the high volume traffic, and to prevent congestion, packet loss and excessive latency.

Storage traffic can use different transport mechanisms, including NFS, POSIX, and RoCEv2. For RoCEv2 the same Load Balancing and Class of Service mechanisms described for the GPU Backend fabric must be implemented. These are described in the "Load Balancing" on page 39 and "Congestion Management" on page 36 sections of this document.

The devices and connectivity in the Storage fabric validated in this JVD are summarized in the following tables:

Table 18: Validated Storage Fabric leaf and spine nodes

Storage Fabric Leaf Nodes switch model	Storage Fabric Spine Nodes switch model
QFX5130-32CD	QFX5130-32CD
QFX5220-32CD	QFX5220-32CD
QFX5230-32CD	QFX5230-32CD
QFX5230-64CD	QFX5230-64CD

(Continued)

Storage Fabric Leaf Nodes switch model	Storage Fabric Spine Nodes switch model
QFX5240-64OD	QFX5240-64OD

Table 19: Validated connections between GPU servers, and storage devices, and leaf nodes in the Storage Fabric

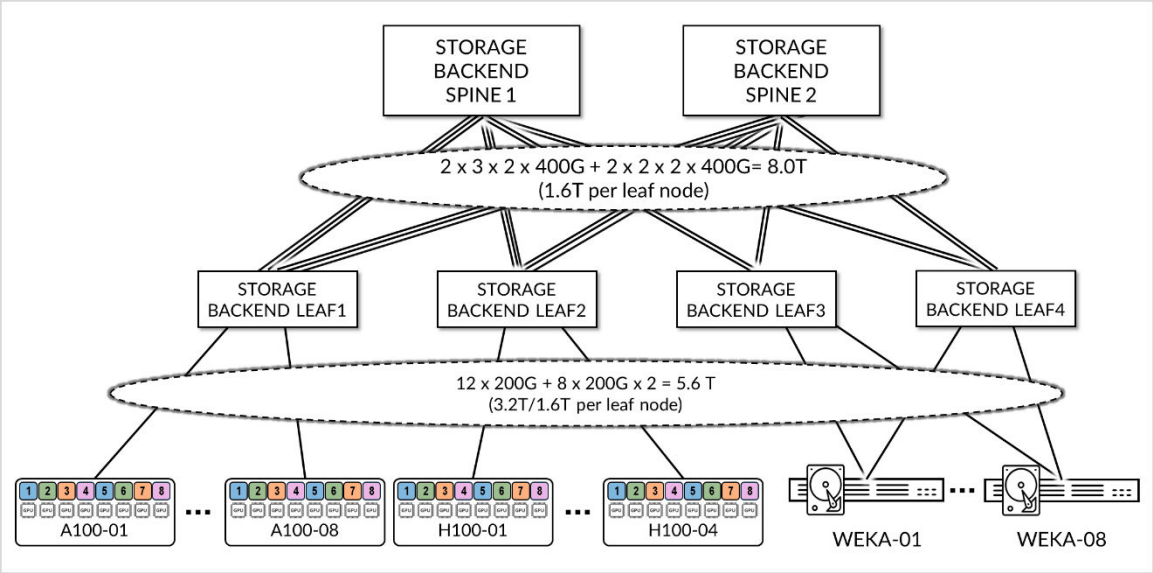
Links per GPU server to leaf connection	Server Type
1 x 100GE	NVIDIA A100
1 x 100GE	NVIDIA H100
1 x 200GE	WEKA

Table 20: Validated connections between leaf and spine nodes in the Storage Fabric

Links per leaf and spine connection	Leaf node model	spine node model
2 x 400GE, 3 x 400GE	QFX5130-32CD	QFX5130-32CD
2 x 400GE, 3 x 400GE	QFX5130-32CD	QFX5130-32CD
2 x 400GE, 3 x 400GE	QFX5240-32CD QFX5241-32CD	QFX5240-32CD QFX5241-32CD

Testing for this JVD was performed using 8 NVIDIA A100 GPU servers, 4 NVIDIA H100 GPU servers, and 8 WEKA storage devices connected to 4 leaf nodes, which in turn were connected to 2 spine nodes as shown in Figure 18.

Figure 18: Storage Fabric JVD Testing Topology



- Each Nvidia A100 server is connected to the Leaf nodes using 200G interfaces (ConnectX-7 NICs).
- Each Nvidia H100 server is connected to the Leaf nodes using 400G interfaces (ConnectX-7 NICs).
- Each Weka device

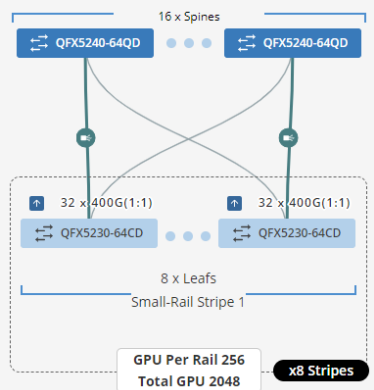
Table 21: Aggregate Storage Link Counts and bandwidth tested

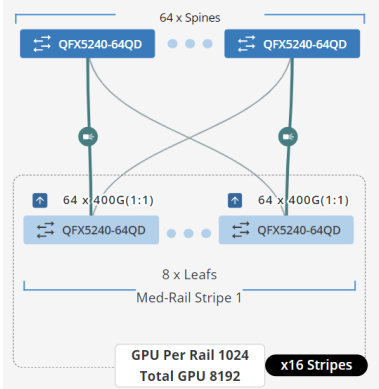
GPU Servers <=> Storage Leaf Nodes	**Storage Leaf Nodes <=> Frontend Spine Nodes**
• Total number of 200GE links between GPU servers and storage leaf nodes = 12 (1 link per server) • Total number of 200GE links between Vast storage devices and storage leaf nodes (2 links per devices) = 16	Total number of 400GE links between frontend leaf nodes and spine nodes = 20 (2-3 links per leaf to spine connection)
Total bandwidth = 5.6 Tbps	Total bandwidth = 6.4 Tbps
	No oversubscription.

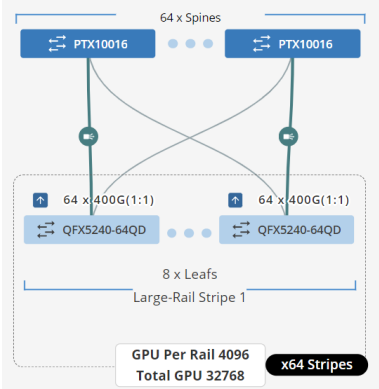
GPU Backend Fabric Scaling

The size of an AI cluster varies significantly depending on the specific requirements of the workload. The number of nodes in an AI cluster is influenced by factors such as the complexity of the machine learning models, the size of the datasets, the desired training speed, and the available budget. The number varies from a small cluster with less than 100 nodes to a data center-wide cluster comprising 10000s of compute, storage, and networking nodes. A minimum of 4 spines must always be deployed for path diversity and reduction of PFC failure paths.

Table 22: Fabric Scaling - Devices and Positioning

Small	Medium	Large
64 – 2048 GPU	2048 – 8192 GPU	8192 – 32768 GPU
With support for up to 2048 GPUs, the Juniper QFX5240-64CD/ QFX5240-64OD/QD or QFX5230-64CD can be used as Spine and leaf devices to support single or dual-stripe applications. To follow best practice recommendations, a minimum of 4 Spines should be deployed, even in a single-stripe fabric.	With support for 2048 – 8192 GPUs, the Juniper QFX5240-64CD/ QFX5240-64OD/QD can be used as Spine and leaf devices to achieve appropriate scale. This 3-stage, rail-based fabric design provides physical connectivity to 16 Stripes from 64 Spines and 1024 leaf nodes, maintaining a 1:1 subscription throughput model.	For infrastructures supporting more than 8192 GPUs, the Juniper PTX1000x Chassis spine and QFX5240-64CD/ QFX5240-64OD/QD leaf nodes can support up to 32768 GPUs. This 3-stage, rail-based fabric design provides physical connectivity to 64 Stripes from 64 Spines and 4096 leaf nodes, maintaining a 1:1 subscription throughput model.
		






Juniper Hardware and Software Components

For this solution design, the Juniper products and software versions are below. The design documented in this JVD is considered the baseline representation for the validated solution. As part of a complete solutions suite, we routinely swap hardware devices with other models during iterative use case testing. Each switch platform validated in this document goes through the same rigorous role-based testing using specified versions of Junos OS and Apstra management software.

Validated Juniper Hardware and Software Solution Components

The following table summarizes the validated Juniper devices for this JVD, and includes devices tested for AI Data Center Network with Juniper Apstra, AMD GPUs, and Vast Storage—Juniper Validated Design (JVD)

Table 23: Validated Devices and Positioning

DEVICE	FRONTEND FABRIC		GPU BACKEND FABRIC		STORAGE FABRIC	
LEAF	SPINE	LEAF	SPINE	LEAF	SPINE	
QFX5130-32CD	X	X			X	X
QFX5220-32CD	X	X	X		X	X
QFX5230-32CD			X		X	X

AI Fabric IP Services

IN THIS SECTION

In the next few sections, we describe the various strategies that can be employed to handle traffic congestion and traffic load distribution in the Backend GPU fabric.

Congestion Management

AI clusters pose unique demands on network infrastructure due to their high-density, and low-entropy traffic patterns, characterized by frequent elephant flows with minimal flow variation. Additionally, most AI modes require uninterrupted packet flow with no packet loss for training jobs to be completed.

For these reasons, when designing a network infrastructure for AI traffic flows, the key objectives include maximum throughput, minimal latency, and minimal network interference over a lossless fabric, resulting in the need to configure effective congestion control methods.

Data Center Quantized Congestion Notification (DCQCN) has become the industry-standard for end-to-end congestion control for RDMA over Converged Ethernet (RoCEv2) traffic. DCQCN congestion control methods offer techniques to strike a balance between reducing traffic rates and stopping traffic all together to alleviate congestion, without resorting to packet drops.

It is important to note that DCQCN is primarily required in the GPU backend fabric, where the majority of AI workload traffic resides, while it is generally unnecessary in the frontend or storage backend."

DCQCN combines two different mechanisms for flow and congestion control:

- Priority-Based Flow Control (PFC), and
- Explicit Congestion Notification (ECN).

Priority-Based Flow Control (PFC)

Priority-Based Flow Control (PFC) is a standard (IEEE 802.1Qbb) backpressure mechanism for Ethernet network devices that signals congestion and causes traffic on a particular priority to temporarily stop packet drops. PFC helps relieve congestion by halting traffic flow for individual traffic priorities (IEEE 802.1p or DSCP markings) mapped to specific queues or ports.

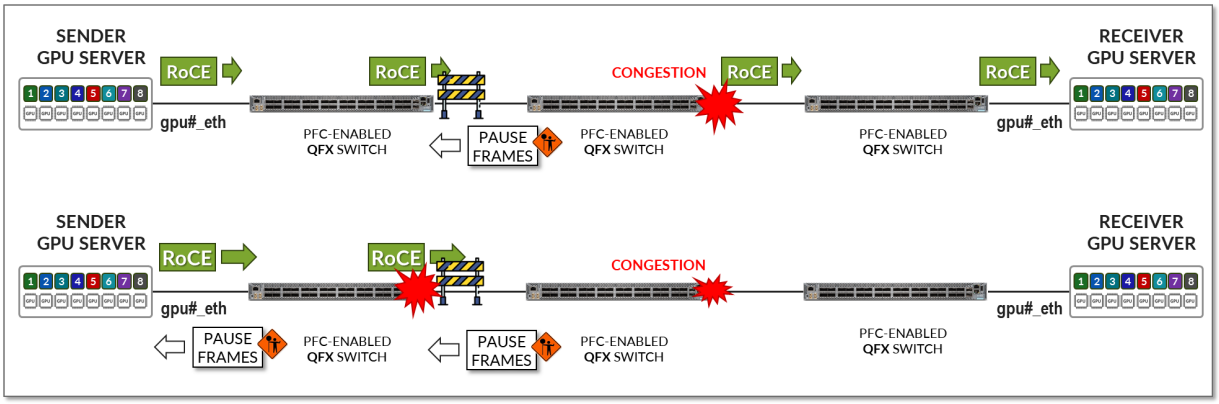
The goal of PFC is to stop a neighbor from sending traffic for a defined amount of time (PAUSE time), or until congestion clears. This process consists of sending PAUSE control frames upstream, requesting the sender to halt transmission of all traffic for a specific class or priority while congestion is ongoing. The sender completely stops sending traffic to the receiving device for the specified priority.

For RoCE traffic, PFC relies on fabric switches detecting congestion and generating PFC Pause frames upstream, and devices that can respond to these frames, including the sending NIC, which receives the PFC Pause frames and reacts accordingly.

While PFC mitigates data loss and allows the receiver to catch up on processing packets already in the queue, it impacts the performance of applications using the affected queues during the congestion period. Additionally, resuming traffic transmission of post-congestion often triggers a surge, potentially exacerbating or reinstating the congestion scenario.

We recommend configuring PFC only on the QFX devices acting as leaf nodes.

Figure 20: *DCQCN – PFC Operation*



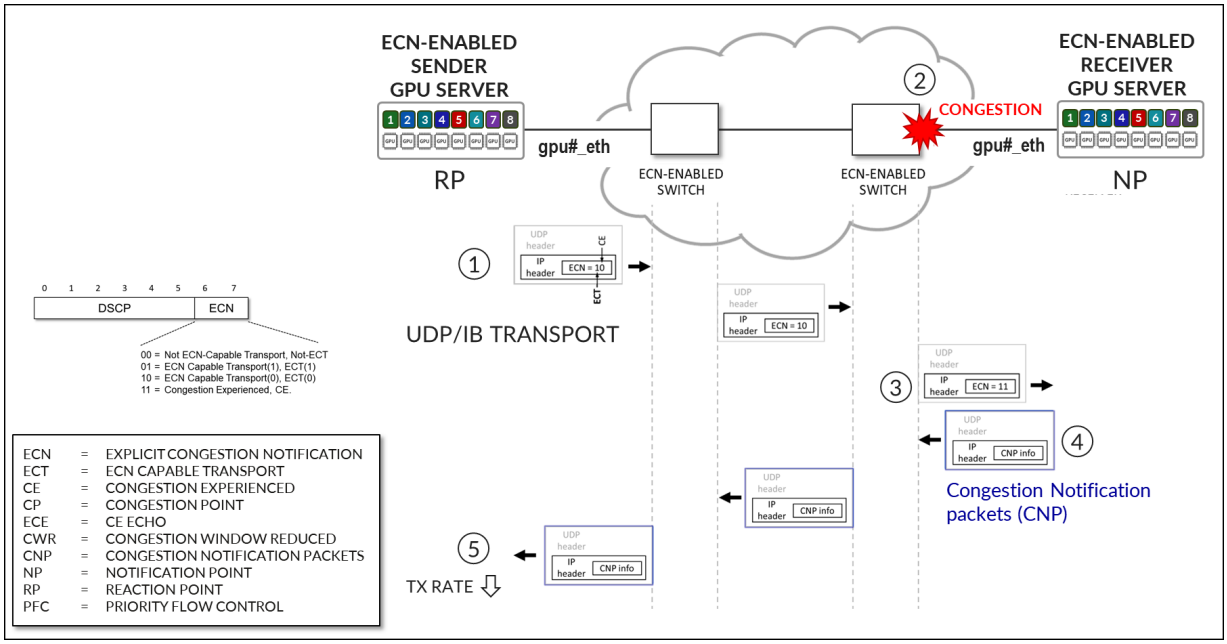
Explicit Congestion Notification (ECN)

Explicit Congestion Notification (ECN) is a standard (RFC 3168) backpressure mechanism for Ethernet network devices that signals congestion and causes traffic to temporarily slow down to avoid packet drops. ECN curtails transmit rates during congestion while enabling traffic to persist, albeit at reduced rates, until congestion subsides. The goal of ECN is to reduce packet loss and delay by making the traffic source decrease the transmission rate until the congestion clears.

This process entails marking packets with ECN bits at congestion points by setting the ECN bits to 11 in the IP header. The presence of this ECN marking prompts receivers to generate Congestion Notification Packets (CNPs) sent back to the source, which signals the source to throttle traffic rates.

ECN for RoCE traffic relies on fabric switches that can detect congestion and implement ECN marking for traffic downstream, and devices that can respond to these markings, as shown in Figure 21:

Figure 21: DCQCN – *ECN Operation*



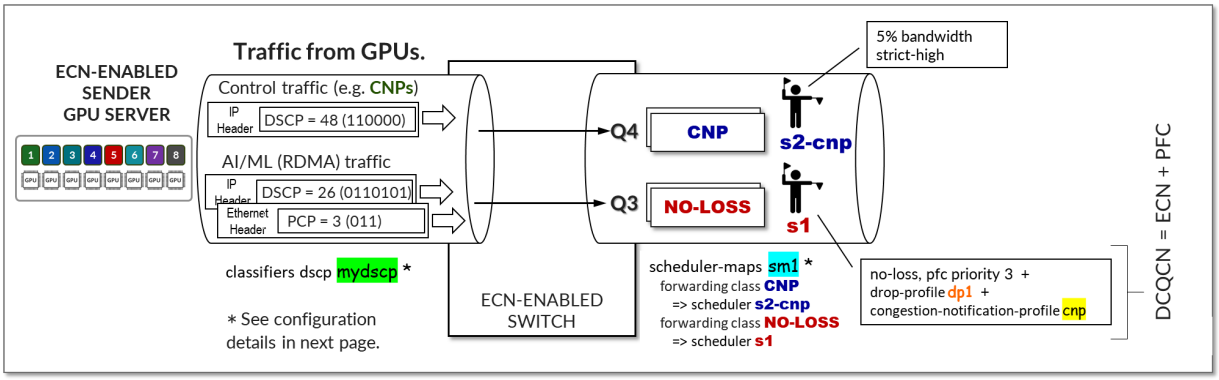
- The receiving NIC, or Notification Point (NP), which transmits CNPs when receiving ECN-marked packets
- The sending NIC, or Reaction Point (RP), that receives the CNP packets and reacts accordingly

Combining PFC and ECN offers the most effective congestion relief in a lossless IP fabric supporting RoCEv2, while safeguarding against packet loss. To achieve this, when implementing PFC and ECN together, their parameters should be carefully selected so that ECN is triggered before PFC.

TOS/DSCP for RDMA Traffic

RDMA traffic must be properly marked to allow the switch to correctly classify it, and to place it in the lossless queue for proper treatment. Marking can be either DSCP within the IP header, or PCP in the ethernet frame vlan-tag field. Whether DSCP or PCP is used depends on whether the interface between the GPU server and the switch is doing vlan tagging (802.1q) or not. Figure 64 shows how RDMA and CNP are marked differently, and as a result, the fabric switch classified and schedules the two types of packets differently.

Figure 22: TOS/DSCP operation



For more information refer to *Introduction to Congestion Control in Juniper AI Networks* which explores how to build a lossless fabric for AI workloads using DCQCN (ECN and PFC) congestion control methods and DLB. The document was based on DLRM training model as a reference and demonstrates how different congestion parameters such as ECN and PFC counters, input drops and tail drops can be monitored to adjust configuration and build a lossless fabric infrastructure for RoCEv2 traffic.

NOTE: We provide general recommendations and describe the parameters validated in the lab. However, each language model has a unique traffic profile and characteristics. Class of Service and load balancing attributes must be tuned to meet your specific model requirements.

Load Balancing

The fabric architecture used in this JVD in all the fabrics follows the 2-stage clos design, with every leaf node connected to all the available spine nodes, and via multiple interfaces. As a result, multiple paths are available between the leaf and spine nodes to reach other devices.

Equal Cost Multiple Path (ECMP) can lead to suboptimal link utilization when distributing AI traffic. ECMP relies on hashing selected packet header fields to spread flows across available paths; however, AI workloads typically generate large, long-lived flows with highly similar header characteristics (for example, identical source and destination addresses, ports, and protocols). This limited flow diversity

significantly reduces hashing entropy, causing multiple flows to be mapped onto the same link. As a result, certain links become overutilized while others remain underused, increasing the risk of congestion and packet loss. This is particularly critical in the GPU backend fabric, where GPU-to-GPU communication occurs.

To improve the distribution of traffic across all the available paths, either Dynamic Load Balancing (DLB), **Adaptive load balancing (ALB) for ECMP,** or Global Load Balancing (GLB) can be implemented instead of ECMP.

For this, JVD Dynamic Load Balancing flowlet-mode was validated on all the QFX leaf nodes and spines nodes, and Adaptive load balancing (ALB) on the PTX spine nodes. Global Load Balancing is also included as an alternative solution.

Additional testing was conducted on the QFX5240-64OD/QFX5241-64OD to evaluate Selective Dynamic Load Balancing, and Reactive path rebalancing. Notice that these load balancing mechanisms are only available on QFX devices.

Dynamic Load Balancing (DLB)

DLB ensures that all paths are utilized more fairly, by not only looking at the packet headers, but also considering real-time link quality based on port load (link utilization) and port queue depth, when selecting a path. This method provides better results when multiple long-lived flows moving large amounts of data need to be load balanced.

DLB can be configured in two different modes:

- **Per packet mode**: packets from the same flow are sprayed across link members of an IP ECMP group, which can cause packets to arrive out of order.
- **Flowlet Mode**: packets from the same flow are sent across a link member of an IP ECMP group. A flowlet is defined as bursts of the same flow separated by periods of inactivity. If a flow pauses for longer than the configured inactivity timer, it is possible to reevaluate the link members' quality, and for the flow to be reassigned to a different.

Adaptive load balancing (ALB):

Adaptive Load Balancing (ALB) is a feedback-driven mechanism designed to detect and correct traffic imbalances across equal-cost paths, improving link utilization beyond what is achievable with static hash-based forwarding. Rather than relying solely on fixed ECMP hashing, ALB continuously evaluates traffic distribution and dynamically adjusts forwarding behavior to mitigate overload conditions and promote fair use of available links.

ALB operates by monitoring packet and byte rates associated with hash buckets and their corresponding next-hop mappings. An adaptive monitoring process, running in the ukernel, periodically scans all next-hops for which ALB is enabled. The monitoring interval is user-configurable and can be as short as a few seconds.

During each scan cycle, ALB computes the aggregate traffic rate per next-hop by summing the traffic carried by all hash buckets mapped to that next-hop. This observed rate is compared against the ideal balanced rate. If the deviation exceeds a user-configurable tolerance threshold, the imbalance compensation algorithm is triggered.

When imbalance is detected, ALB takes corrective action by reprogramming the selector (hash bucket–to–next-hop mapping) to shift traffic away from heavily utilized next-hops toward less utilized ones. This redistribution process effectively addresses a bin-packing problem, as it seeks to reassign hash buckets in a way that minimizes load variance across links. Due to the computational complexity involved, ALB performs these adjustments incrementally at each monitoring interval.

By default, the monitoring interval is 30 seconds and can be configured from one to five 30-second intervals. During each interval, the control software reads packet and byte counters collected over the most recent two seconds to calculate current traffic rates and inform rebalancing decisions.

The tolerance threshold used to detect imbalance is defined as:

ALB is supported on the PTX10001-36MR, PTX10002-36QDD, PTX10003, PTX10004, PTX10008, and PTX10016 platforms, starting with Junos OS Evolved Release 24.4R1.

Global load balancing (GLB):

GLB is an improvement on DLB which only considers the local link bandwidth utilization. GLB, on the other hand, has visibility into the bandwidth utilization of links at the next-to-next-hop (NNH) level. As a result, GLB can reroute traffic flows to avoid traffic congestion farther out in the network than DLB can detect.

AI-ML data centers have less entropy, and larger data flows than other networks. Because hash-based load balancing does not always effectively load-balance large data flows of traffic with less entropy, dynamic load balancing (DLB) is often used instead. However, DLB considers only the local link bandwidth utilization. For this reason, DLB can effectively mitigate traffic congestion only on the immediate next hop. GLB more effectively load-balances large data flows by taking traffic congestion on remote links into account.

GLB is only supported for QFX-5240 (TH5) starting on 23.4R2 and 24.4R1, requires a full 3-tier CLOS architecture, and is limited to only one link between each spine and leaf. When there is more than one interface or a bundle between a pair of leaf and spine, GLB won't work. Also, GLB supports 64 profiles in the table. This means there can be 64 leaves in the 3-stage Clos topology where GLB is running.

For additional details on the operation and configuration of GLB refer to Avoiding AI/ML traffic congestion with global load balancing | HPE Juniper Networking Blogs

ADDITIONAL REFERENCES:

Introduction to Congestion Control in Juniper AI Networks explores how to build a lossless fabric for AI workloads using DCQCN (ECN and PFC) congestion control methods and DLB. The document was based on DLRM training model as a reference and demonstrates how different congestion parameters such as ECN and PFC counters, input drops and tail drops can be monitored to adjust configuration and build a lossless fabric infrastructure for RoCEv2 traffic.

Load Balancing in the Data Center provides a comprehensive deep dive into the various load-balancing mechanisms and their evolution to suit the needs of the data center.

Fabric configuration Walkthrough using Juniper Apstra

IN THIS SECTION

This section describes the steps to deploy one of the AI GPU Backend IP fabrics in the AI JVD lab, as an example of how to deploy new fabrics, using Juniper Apstra.

These steps will cover the AI GPU Backend IP fabric using QFX5220-32CD and QFX5230-64CD switches in the spine and leaf role. Similar steps should be followed to set up the Frontend and Storage Backend fabrics.

The section also provides configuration steps for the Nvidia GPU servers.

Setting up the Apstra Server

A configuration wizard launches upon connecting to the Apstra server VM for the first time. At this point, passwords for the Apstra server, Apstra UI, and network configuration can be configured.

For more detailed information about installation and step-by-step configuration with Apstra, refer to the Juniper Apstra User Guide.

Onboarding devices in Apstra

There are two methods for adding Juniper devices into Apstra:

1. Using ZTP
   From the Apstra ZTP server, follow the ZTP steps described in the Juniper Apstra User Guide.
2. Manually (covered in detail in the next section)

NOTE: Apstra imports the configuration from the devices into a baseline configuration called pristine configuration, which is a clean, minimal, and free of any pre-existing settings that could interfere with the intended network design managed by Apstra.

Apstra ignores the Junos configuration 'groups' stanza and does not validate any group configuration listed in the inheritance model, refer to the configuration groups usage guide.

It is best practice to avoid setting loopbacks, interfaces (except management interface), routing-instances (except management-instance) or any other settings as part of this baseline configuration.

Apstra sets the protocols LLDP and RSTP when the device is successfully Acknowledged.

To onboard each device, follow these steps in the **Apstra Web UI**:

Onboarding devices in Apstra steps

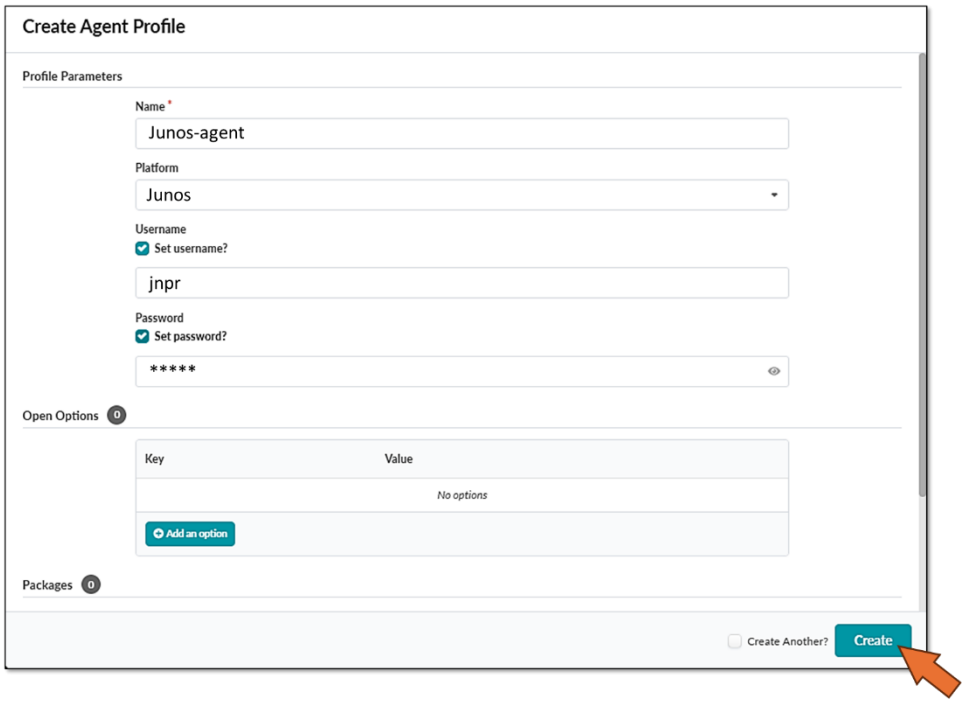
Step 1: Create Agent Profile for Junos devices.

1. Navigate to Devices **>>** Agent Profiles
2. Click on Create Agent Profile.
   Figure 23. Create Agent Profile in Apstra

NOTE: For the purposes of this JVD, the same username and password are used across all devices. Thus, only one Junos Agent Profile is needed to onboard all the devices.

3. Enter the Agent profile name, select platform (Junos), and enter the username and password that will be used by Apstra to communicate with the devices.
   - This requires that the devices are preconfigured with a root password, the username and password configured in Apstra, a management IP and proper static routing if needed, as well as ssh Netconf, so that they can be accessed and configured by Apstra.

Figure 24: Apstra Agent Profile Parameters



4. After entering the required information, click **Create**.
5. Confirm **Agent Profile** creation.

Figure 25: New Apstra Agent Profile Verification

Step 2: Create Agent Profile for other devices.

1. Navigate to **Devices** >> **Agent Profiles**

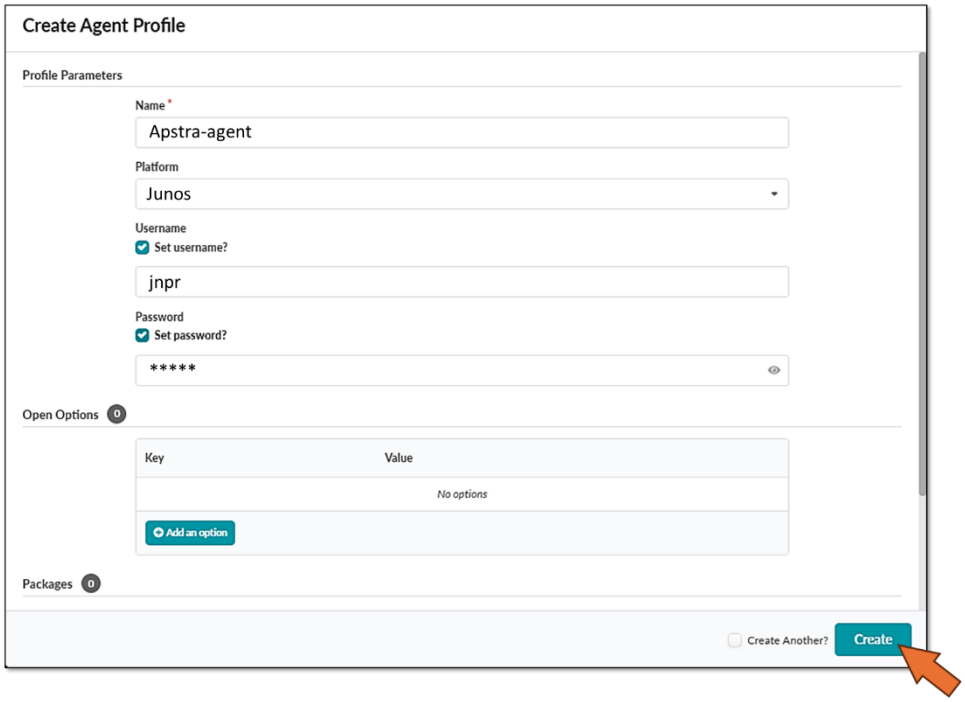
2. Click on **Create Agent Profile**.

   Figure 26. Create Agent Profile in Apstra

3. Enter the Agent profile name, select platform (Junos), and enter the username and password that will be used by Apstra to communicate with the devices.

   This requires that the devices are preconfigured with a root password, the username and password configured in Apstra, a management IP and proper static routing if needed, as well as ssh Netconf, so that they can be accessed and configured by Apstra.

   Figure 27: Apstra Agent Profile Parameters



4. After entering the required information, click **Create**.

5. Confirm **Agent Profile** creation.

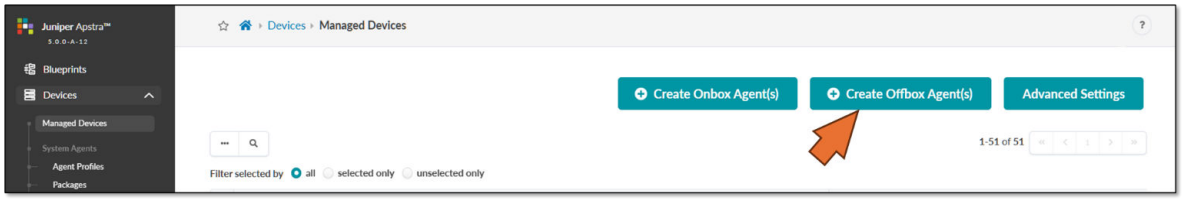
Figure 28: New Apstra Agent Profile Verification

Step 3: Create Offbox Agents for QFX devices.

1. Navigate to **Devices** >> **Managed Devices**

2. Click on **Create Offbox Agents**. Make sure you select **Offbox Agent(s).**

   Figure 29: Create Offbox Agent in Apstra



3. Identify the device(s) to onboard. You can enter a comma-separated list of hostnames, individual IP addresses, or IP address ranges.

   NOTE: An IP address range can also be provided to onboard multiple devices in Apstra at once. The ranges shown in the example below are shown for demonstration purposes only.

4. Select the platform, and **Agent Profile** (select the profile created in the previous step).

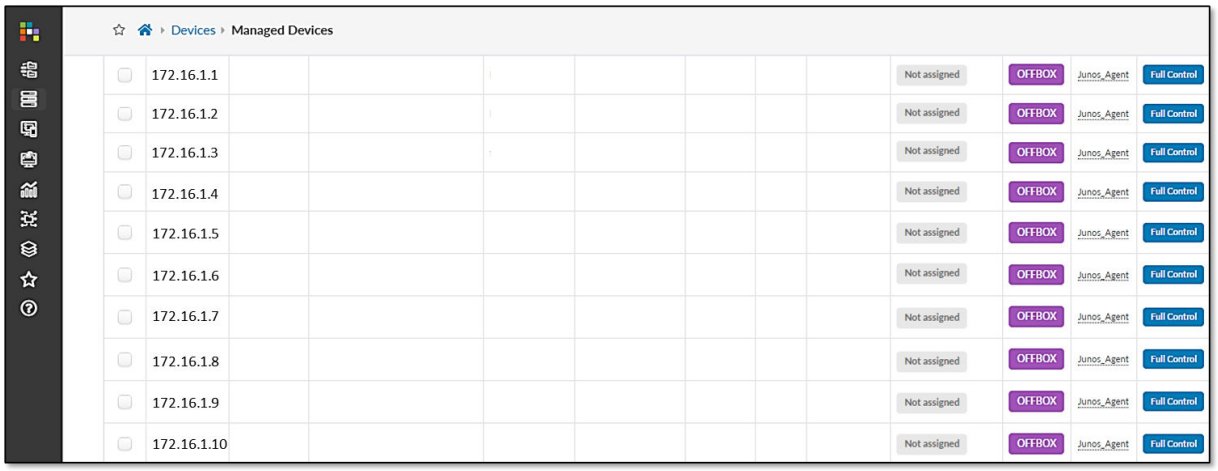
   Figure 30: Identifying the device(s) to onboard using a range of IP Addresses

   NOTE: Apstra uses the information from the profile that was created in the previous step, if " ***Set username?"*** and " ***Set password?"*** are unchecked.

5. Click Create.

6. Confirm that the devices have been added for onboarding. Once the offbox agent has been created, devices will be added to the list of Managed Devices. Apstra will attempt to connect, and if successful, it will populate the relevant information.

Figure 31: New devices being onboarded

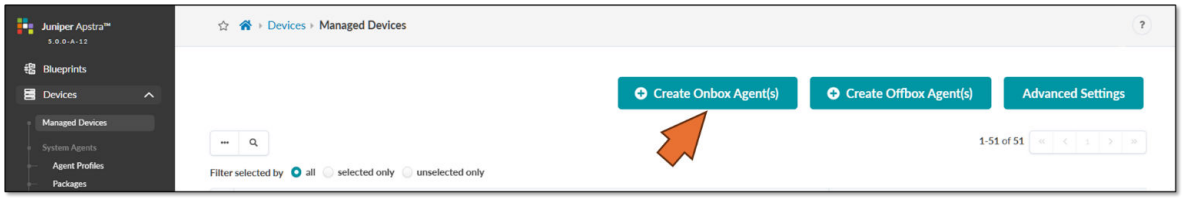


Step 4: Create Onbox Agents and onboard AMD servers.

1. Navigate to **Devices** >> **Managed Devices**

2. Click on **Create Onbox Agents**. Make sure you select **Onbox Agent(s).**

   Figure 32: Create Onbox Agent in Apstra



3. Identify the device(s) to onboard. You can enter a comma-separated list of hostnames, individual IP addresses, or IP address ranges.

   NOTE: An IP address range can also be provided to onboard multiple devices in Apstra at once. The ranges shown in the example below are shown for demonstration purposes only.

4. Select the platform, and **Agent Profile** (select the profile created in the previous step).

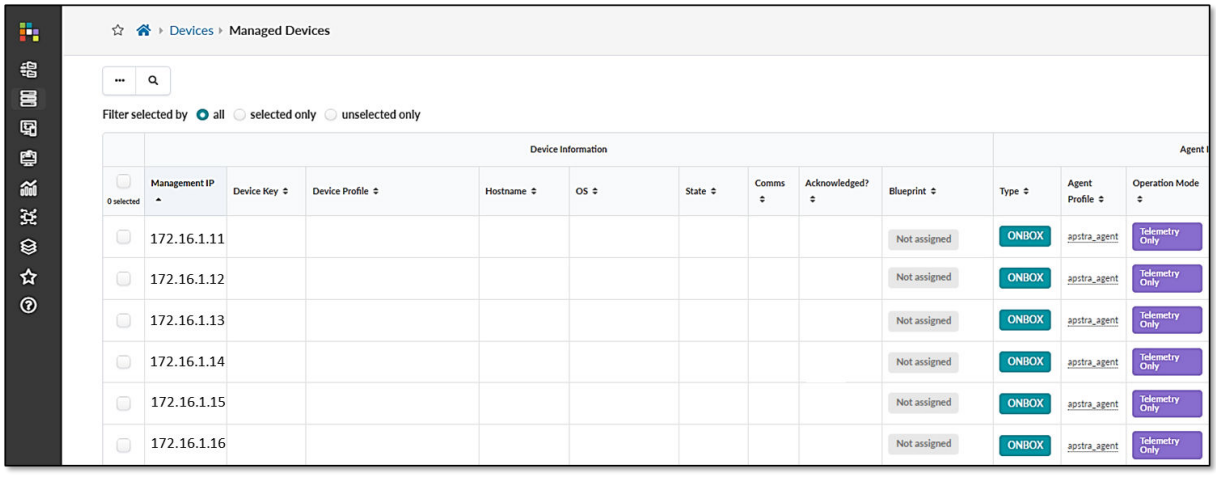
   Figure 33: Identifying the device(s) to onboard using a range of IP Addresses

NOTE: Apstra uses the information from the profile that was created in the previous step, if " ***Set username?"*** and " ***Set password?"*** are unchecked,

5. Click Create.

6. Confirm that the devices have been added for onboarding. Once the onbox agent has been created, devices will be added to the list of Managed Devices. Apstra will attempt to connect, and if successful, it will populate the relevant information.

Figure 34: New devices being onboarded



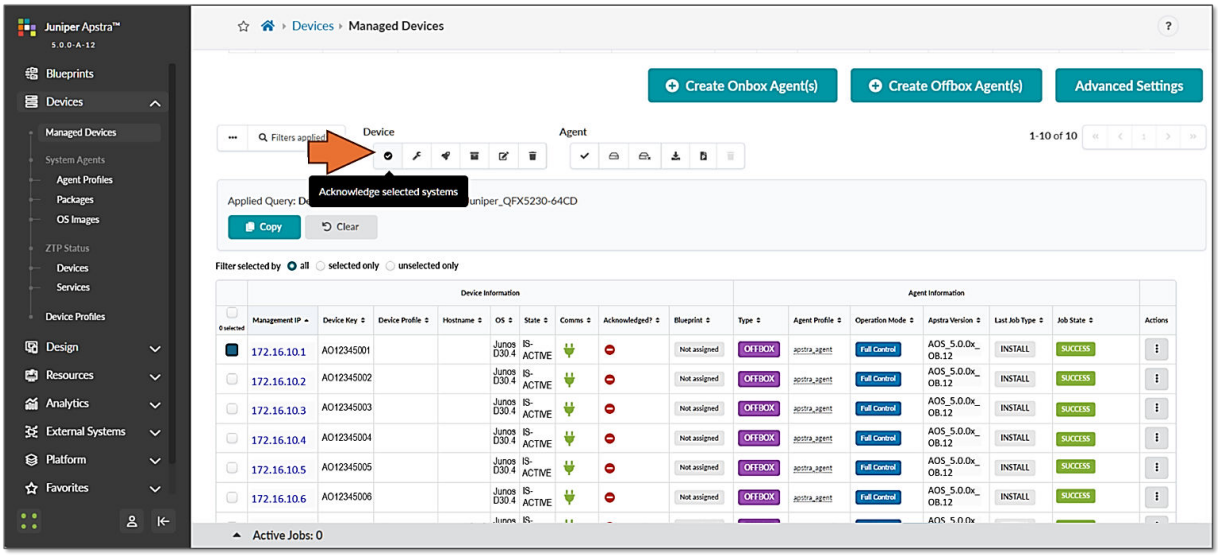
Step 5: Acknowledge Managed Devices for Use in Apstra Blueprints.

The devices must be acknowledged by the user to complete the onboarding and allow them to be part of Apstra Blueprints.

Once the offbox agent creation has been successfully executed for each device, the devices must be acknowledged by the user to complete the onboarding and make them part of the Apstra Blueprints. This moves the device state from OOS-QUARANTINE to OOS-READY.

1. Select device(s)
2. Click on the “Acknowledge selected system button”

Figure 35: Acknowledging Managed Devices in Apstra Blueprints



Fabric Provisioning in the Apstra Web UI

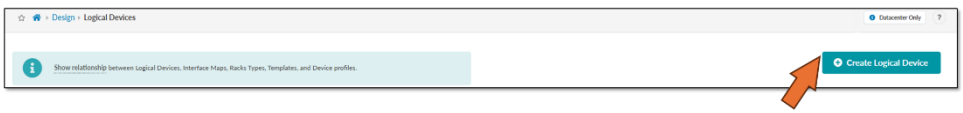
To provision the fabric, follow these steps in the **Apstra Web UI**:

NOTE: The steps are demonstrated using the GPU Backend Fabric as an example.

Step 1: Create Logical Devices and Interface maps for leaf and spine nodes.

The example shows how to create the interface map and Logical device for the PTX10008 with LC1301 spine nodes.

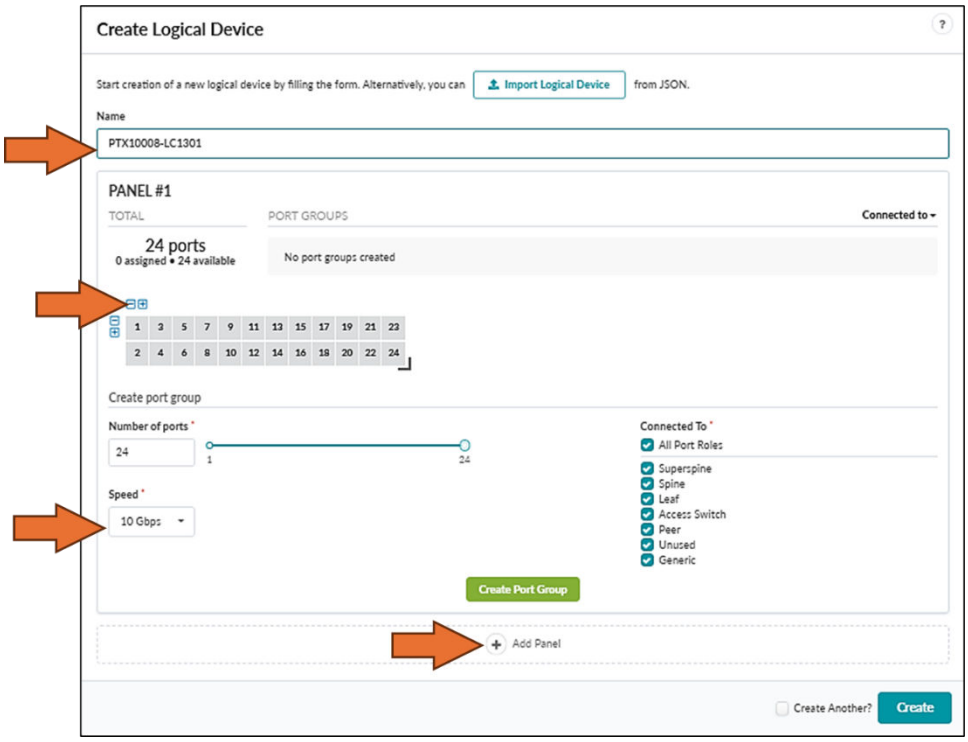
1. Navigate to **Design > Logical Devices**
2. Click on **Create Logical Device.**
   Figure 36: Creating a Logical Device



3. Provide a name, add additional ports, and change the speed to 800G.

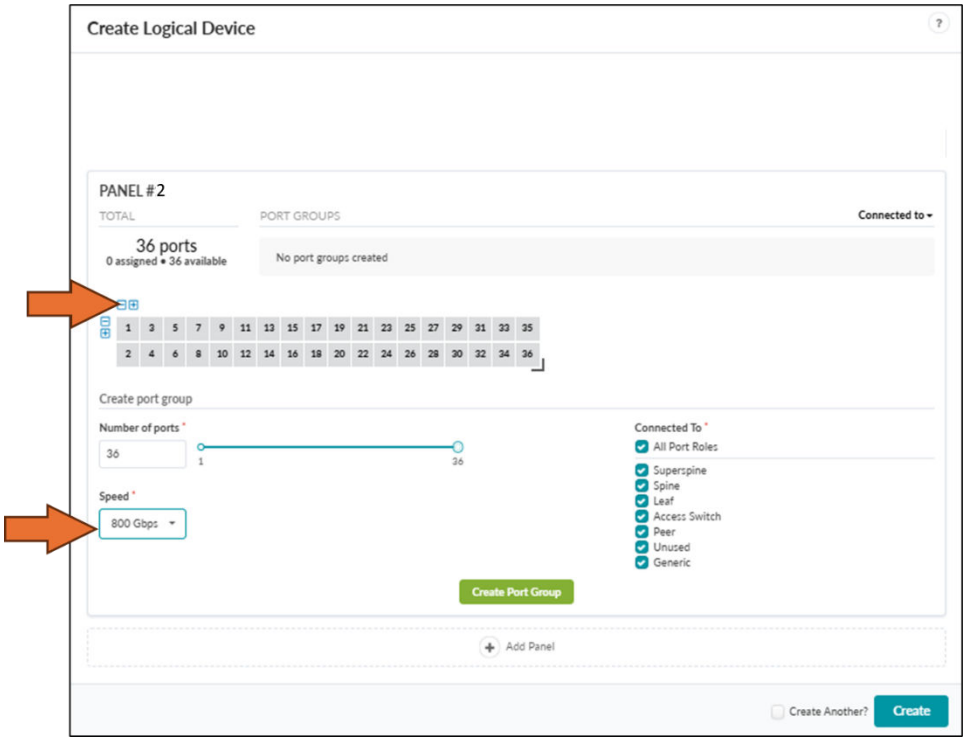
4. Click on **Add Pannel**.

   Figure 37: Creating Logical Device Panel 1.



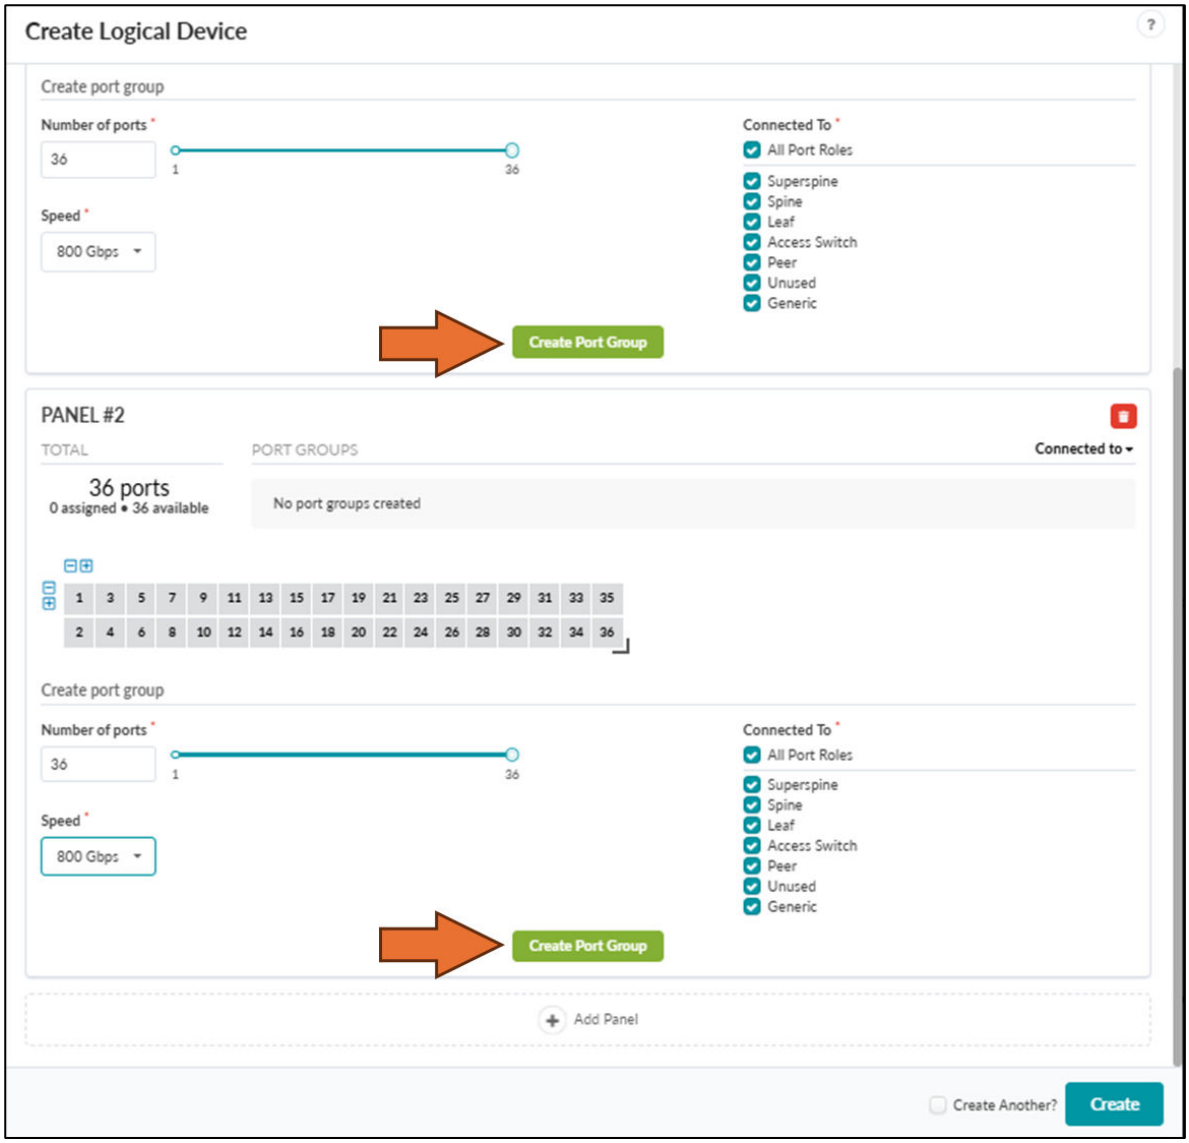
5. Provide a name, add additional ports, and change the speed to 800G on the second panel.

   Figure 38: Creating Logical Device Panel 2.



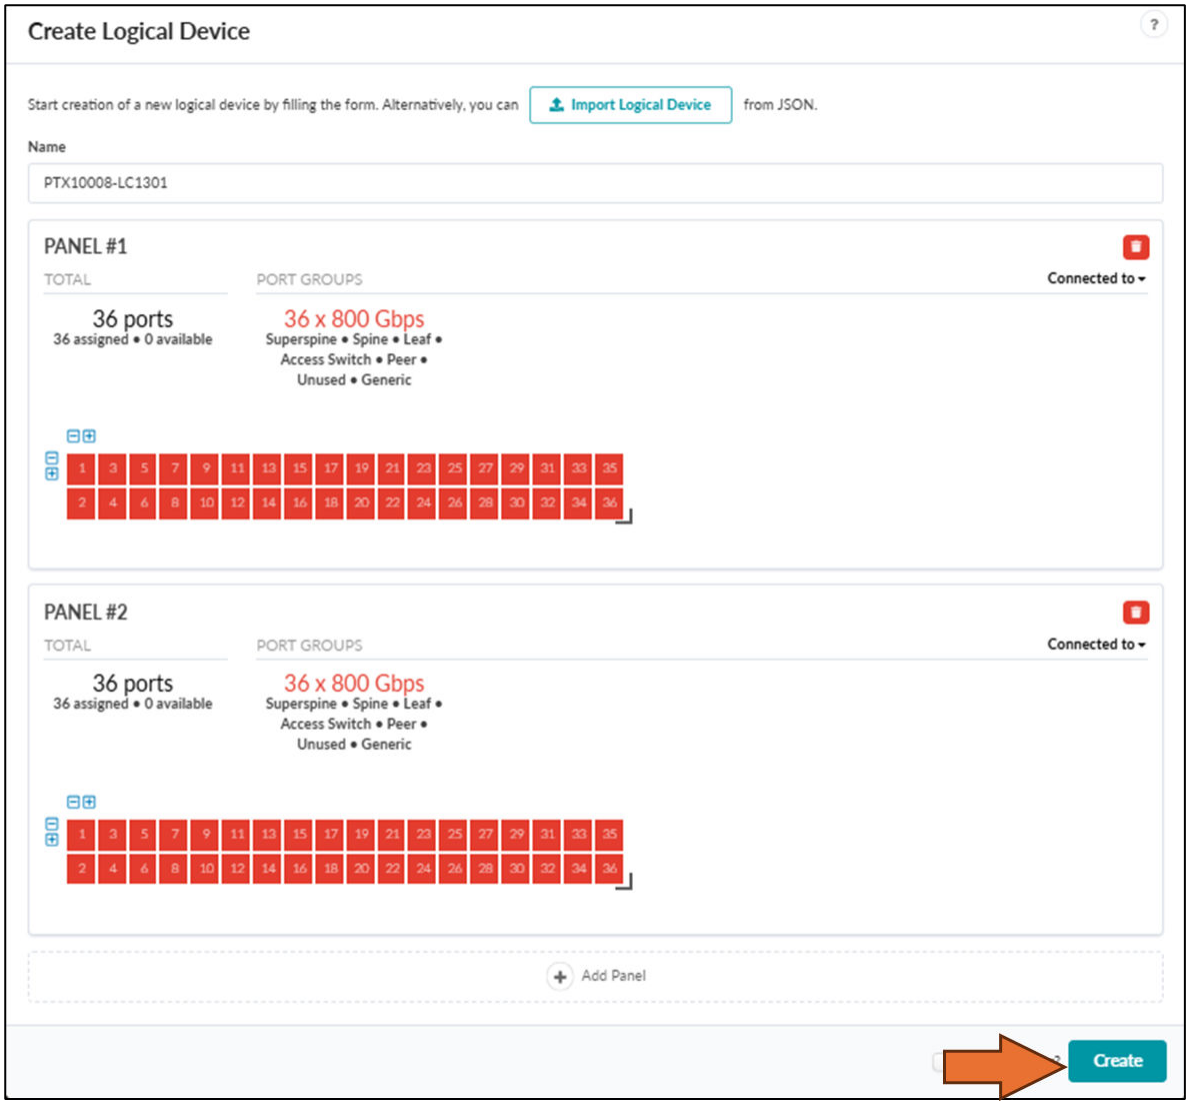
6. Click on **Create Port Group** for panels 1 and 2.

Figure 39: Creating Logical Device Port groups.



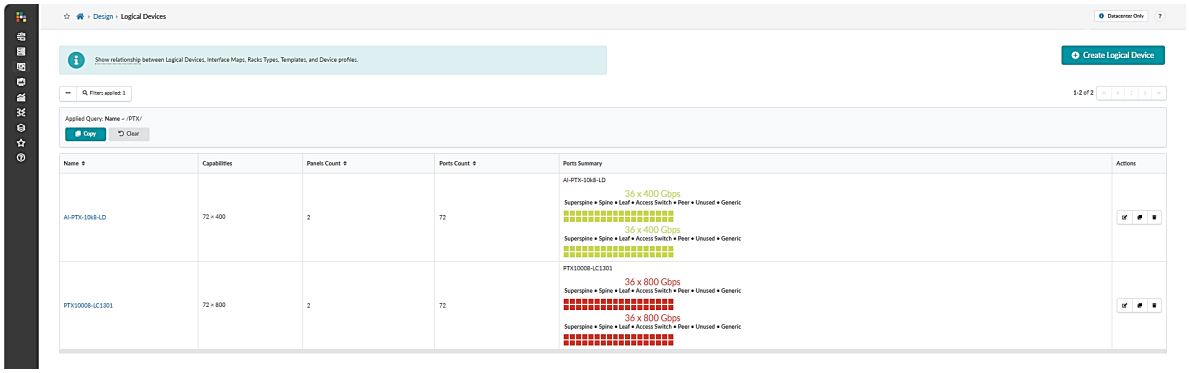
7. Click **Create**.

Figure 40: Creating Logical Device



8. Verify **Logical Device** Creation.

Figure 41: New Logical Device



9. Navigate to **Design > Logical Devices**

Figure 42: Creating an Interface Map

For the QFX5220 leaf nodes, the Logical Device and Interface Map are shown in Figures 43 and 44:

Figure 43: Apstra Logical Device for the QFX5220 Leaf Nodes

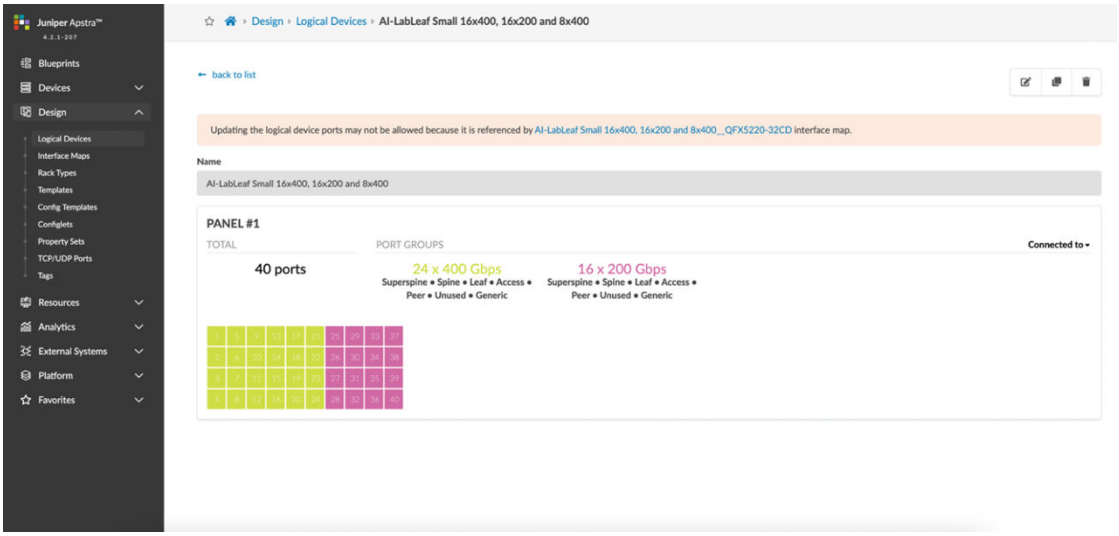


Figure 44: Apstra Interface Map for the QFX5220 Leaf Nodes

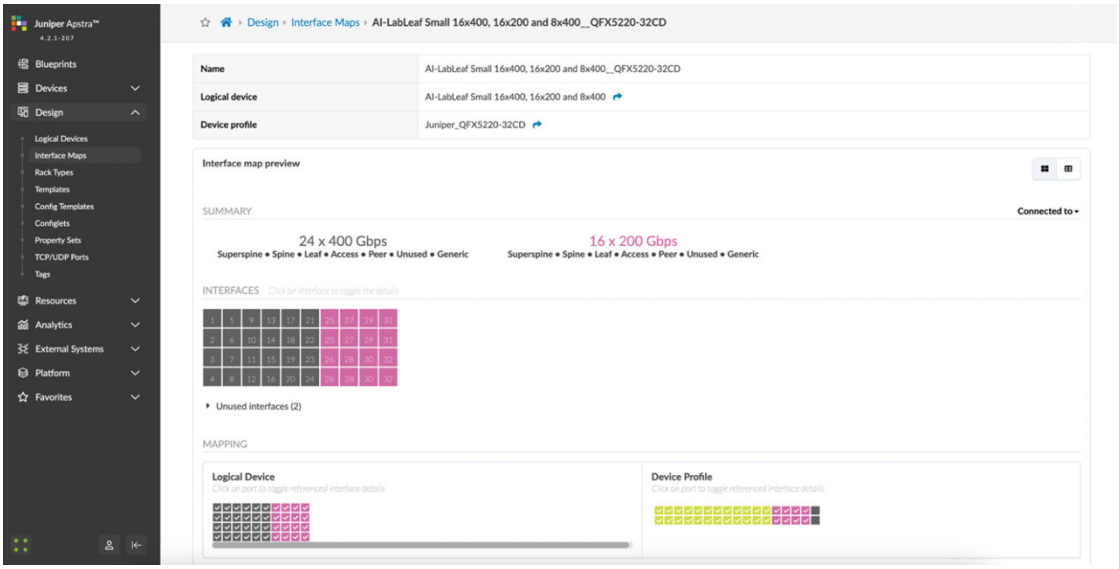

For the QFX5230-64CD leaf nodes, the Logical Device and Interface Map are shown in Figures 45 and 46:

Figure 45: Apstra Logical Device for the QFX5230 Leaf Nodes

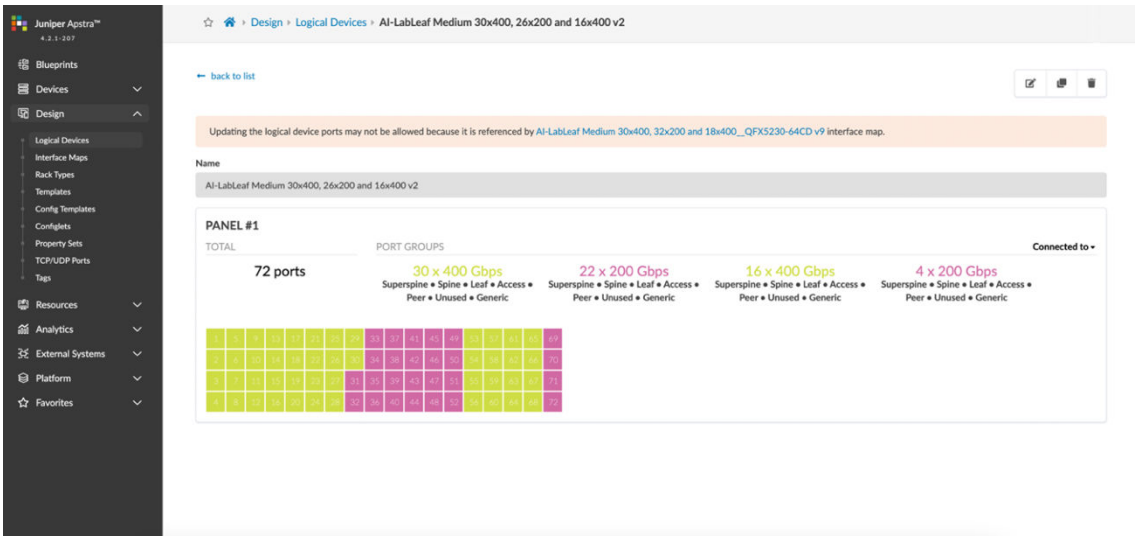

Figure 46: Apstra Interface Map for the QFX5230 Leaf Nodes

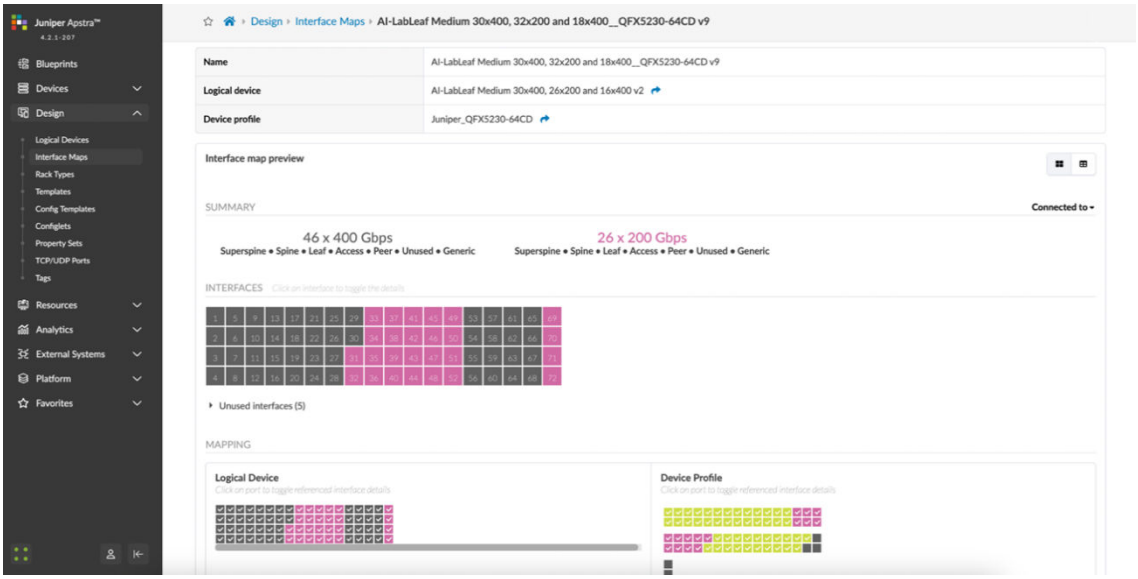

For the QFX5230 spine nodes, the Logical Device and Interface Map are shown in Figures 47 and 48:

Figure 47: Apstra Logical Device for the QFX5230 Spine Nodes

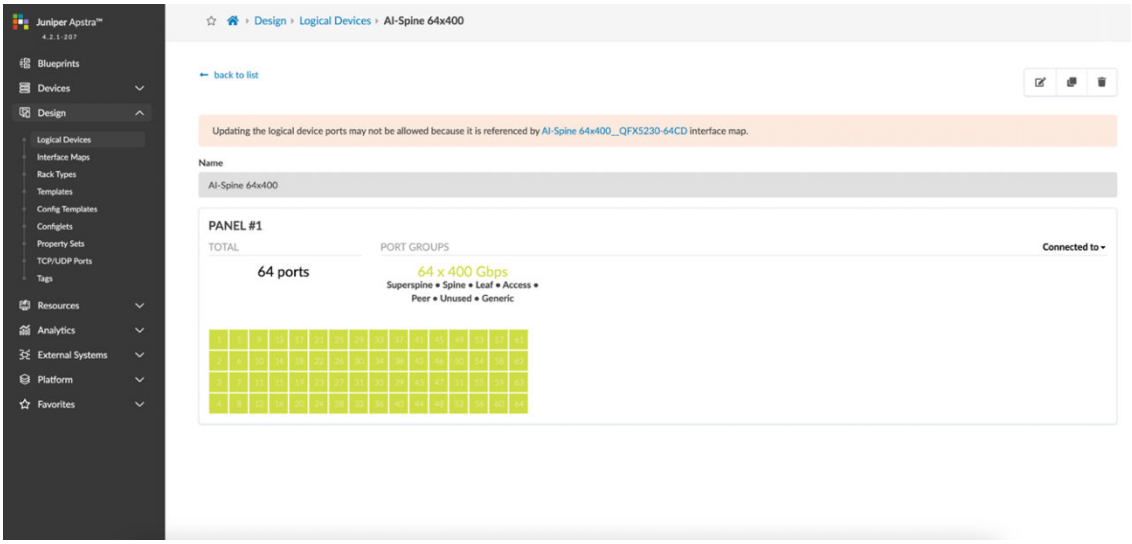

Figure 48: Apstra Interface Map for the QFX5230 Spine Nodes

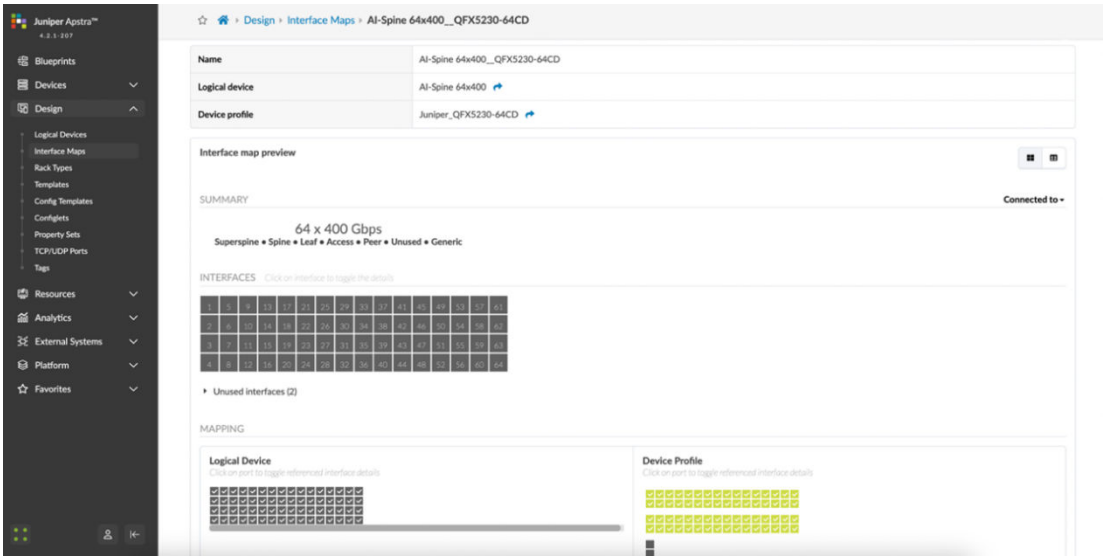

For the QFX5240 spine and leaf nodes, the Logical Device and Interface Map are shown in Figures 49-50 and 51-52 respectively.

NOTE: The QFX5240s port numbering in Junos OS Release 23.4R2 was modified. Table 25 shows the differences between the old and the new port mappings.

The following table shows the differences between the old and the new port mappings.

Table 25. QFX5240-64DC port mappings

OLD PORT MAPPING (22.2X100															
0 (8x100G)	2	4	6	8	10	12	14	16	18	20	22	24	26	28	30
1 (unused)	3	5	7	9	11	13	15	17	19	21	23	25	27	29	31
32 (8x100G)	34	36	38	40	42	44	46	48	50	52	54	56	58	60	62
33 (unused)	35	37	39	41	43	45	47	49	51	53	55	57	59	61	63
NEW PORT MAPPING (23.4R2)															
0 (8x100G)	4	8	12	16	20	24	28	32	36	40	44	48	52	56	60
1 (2x400G or 1x800G)	5	9	13	17	21	25	29	33	37	41	45	49	53	57	61
2 (8x100G)	6	10	14	18	22	26	30	34	38	42	46	50	54	58	62
3 (2x400G or 1x800G)	7	11	15	19	23	27	31	35	39	43	47	51	55	59	63

The Interface Map and Logical Devices for the QFX5240-64DC leaf and spine nodes were created following the new port mapping as shown in Figures 49-50

Figure 49: Apstra Interface Map for the QFX5240 Spine Nodes

Figure 50: Apstra Logical Device for the QFX5240 Spine Nodes

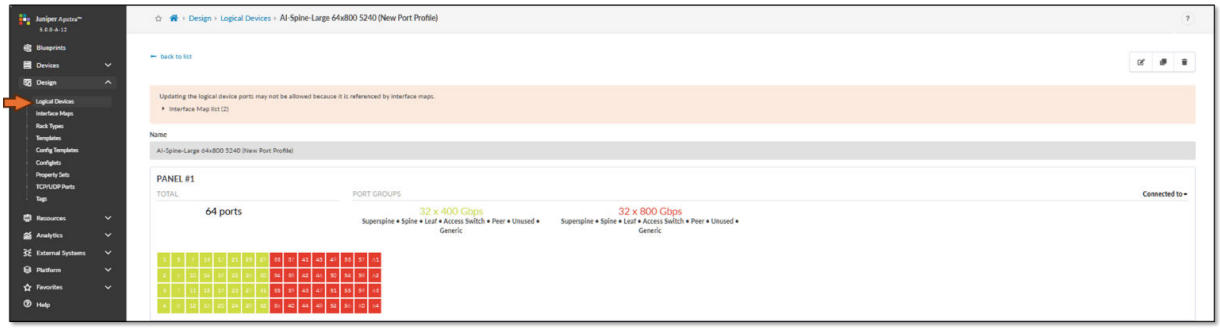

Figure 51: Apstra Interface Map for the QFX5240 Leaf Nodes

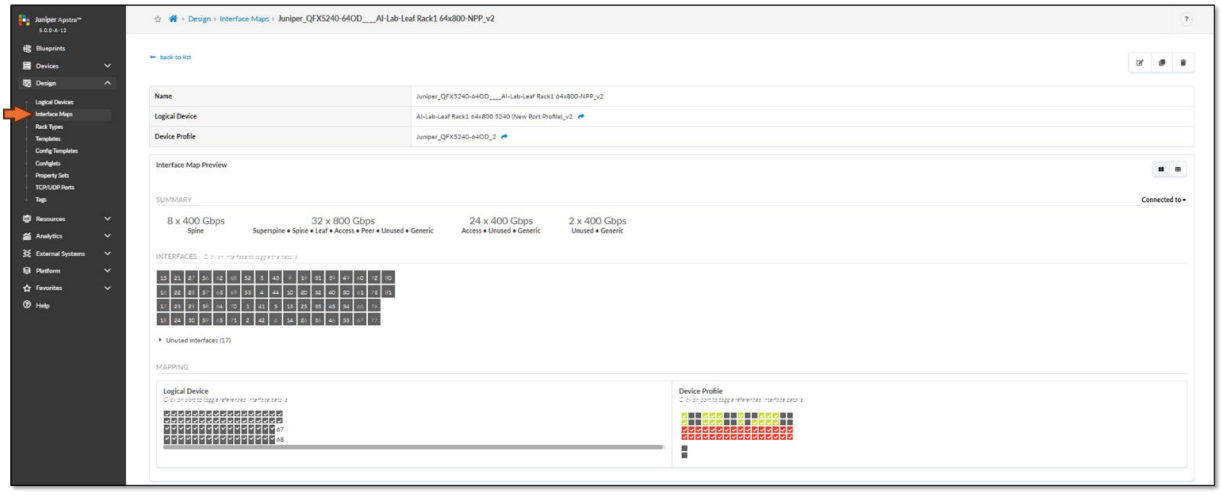

Figure 52: Apstra Logical Device for the QFX5240 Leaf Nodes

For the PTX10008 LC1201 spine nodes also tested, the Logical Device and Interface Map are shown in Figures 53-54.

Figure 53: Apstra Interface Map for the PTX Spine Nodes

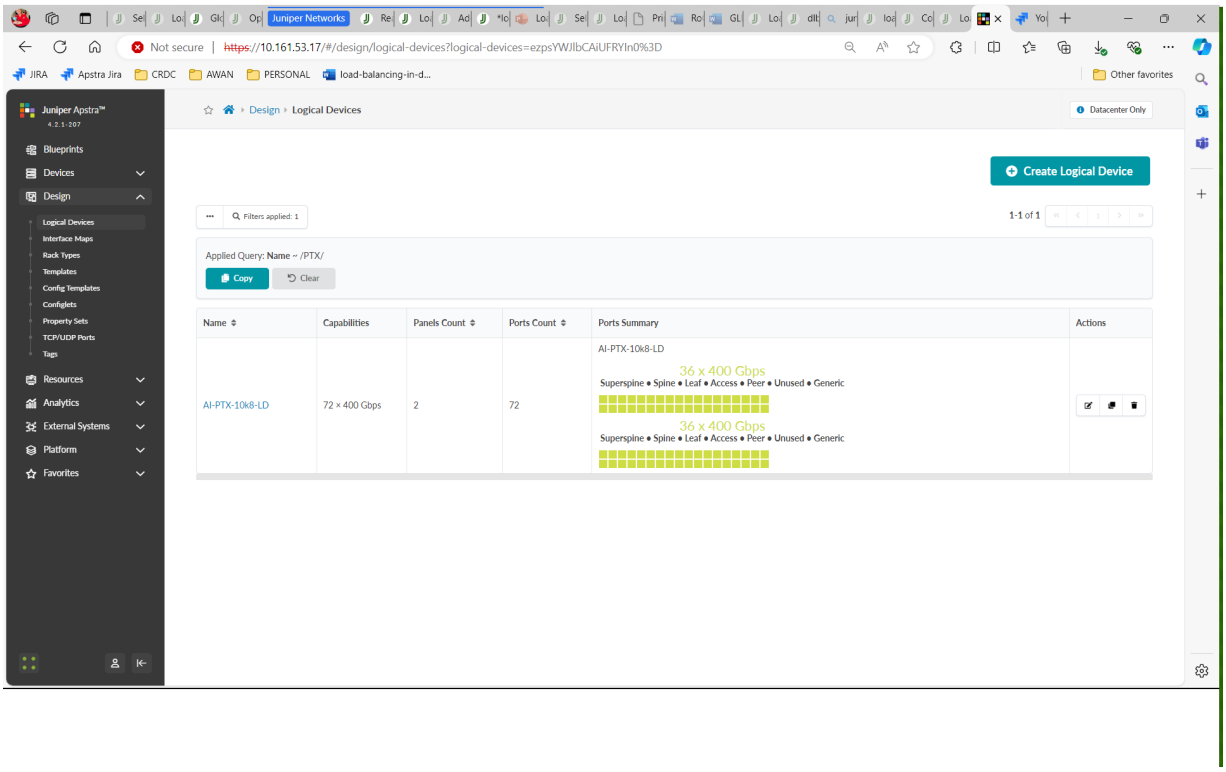

Figure 54: Apstra Logical Device for the PTX Spine Nodes

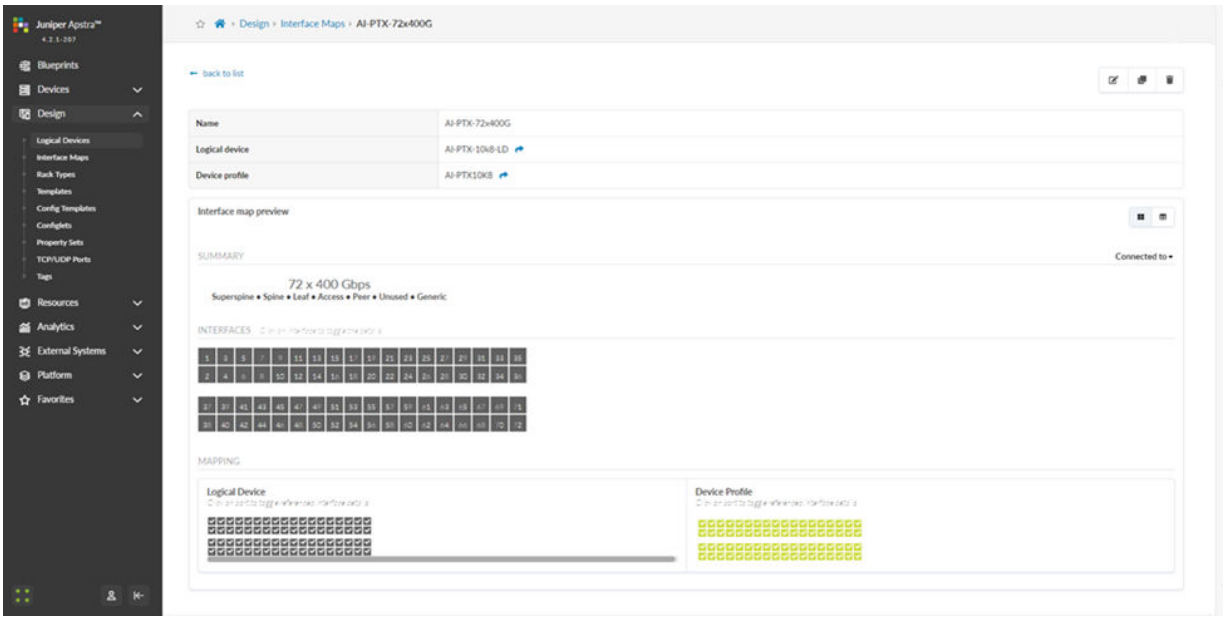

Step 2: Create Interface Map and Logical Device for the GPU servers

The logical Device and Interface Map for the AMD NVIDIA GPU servers are shown in Figures 55-56, respectively.

Figure 55: Apstra Interface Map for the A100 Nvidia Servers

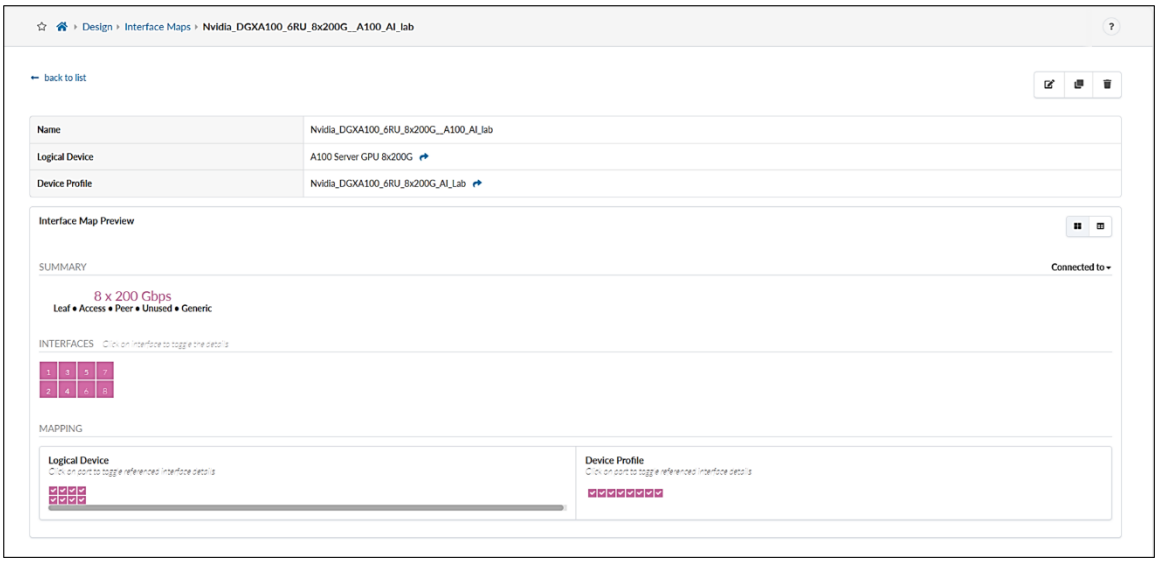

Figure 56: Apstra Interface Map for the H100 Nvidia Servers

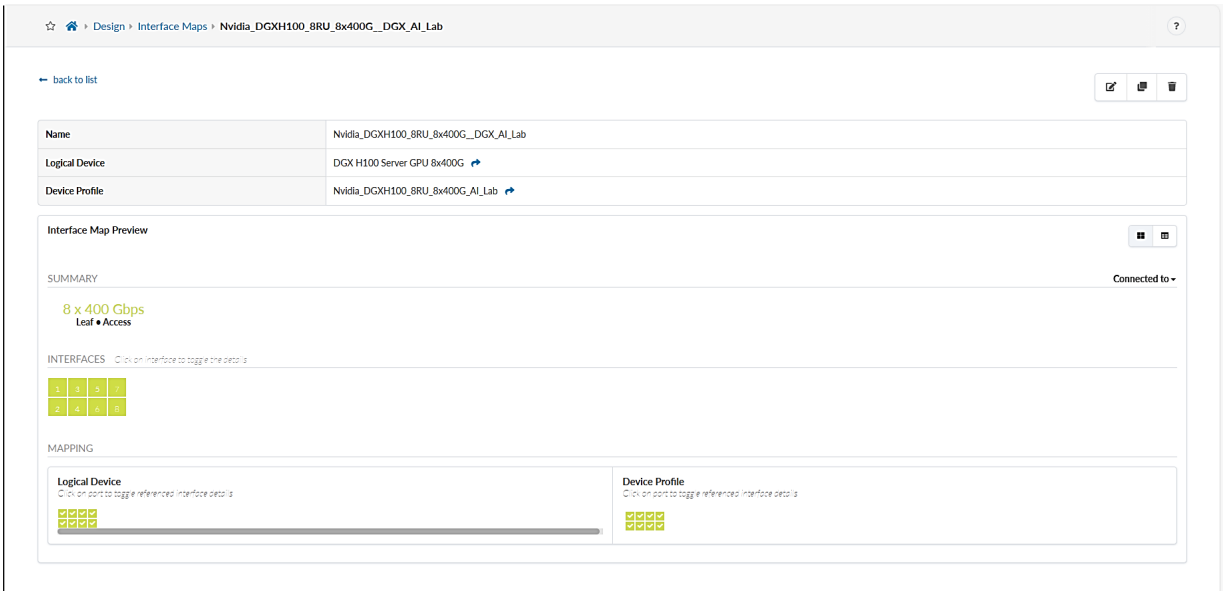

Figure 57: Logical Devices for the A100 Nvidia Servers

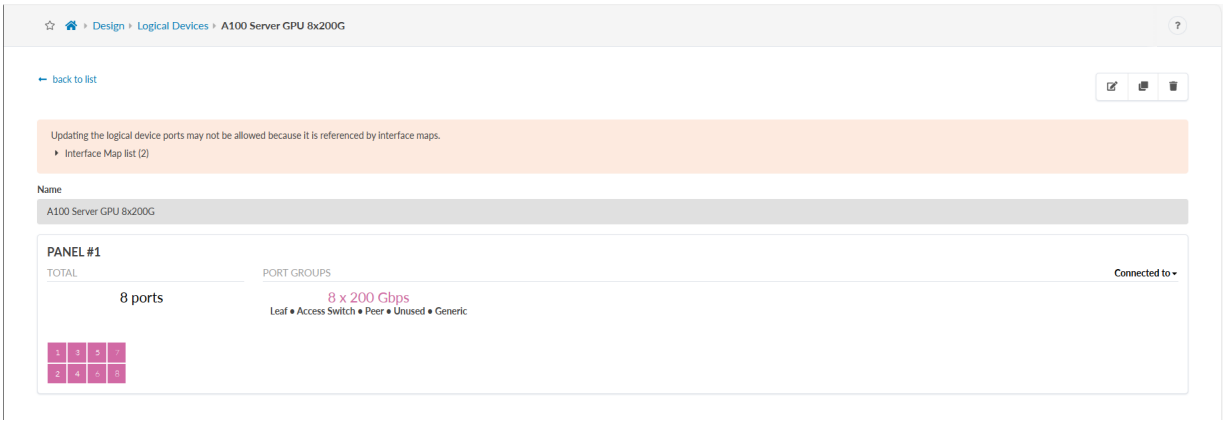

Figure 58: Logical Devices for the H100 Nvidia Servers

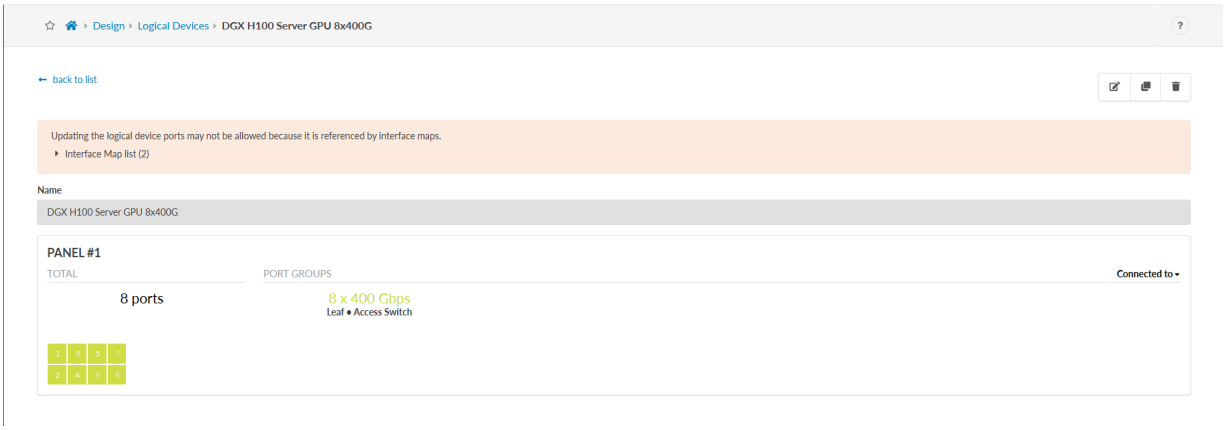


Step 3. Create Rack type for the GPU Backend Fabric

1. Navigate to **Design → Rack Types → Create in Builder**

   NOTE: In Apstra, a Rack is technically equivalent to a stripe in the context of an AI Fabric

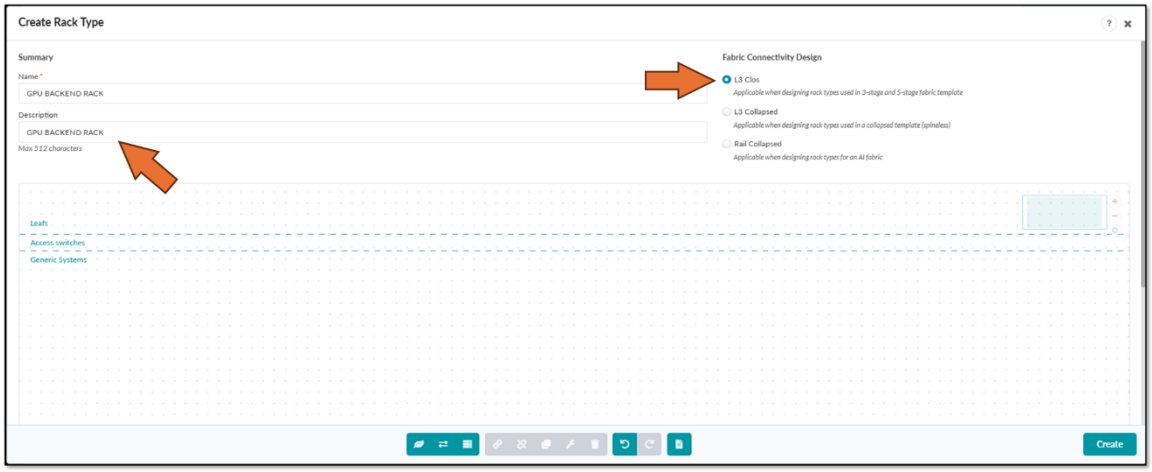
2. Click on **Create Rack Type**

   Figure 59: Create Rack Type in Apstra

   NOTE: You can choose between Create In Builder or Create In Designer (graphical version). We demonstrate the Create In Builder option here.

3. Provide a name and description and select L3 Clos.

   Figure 60: Creating a Rack in Apstra using the Create In Builder option.



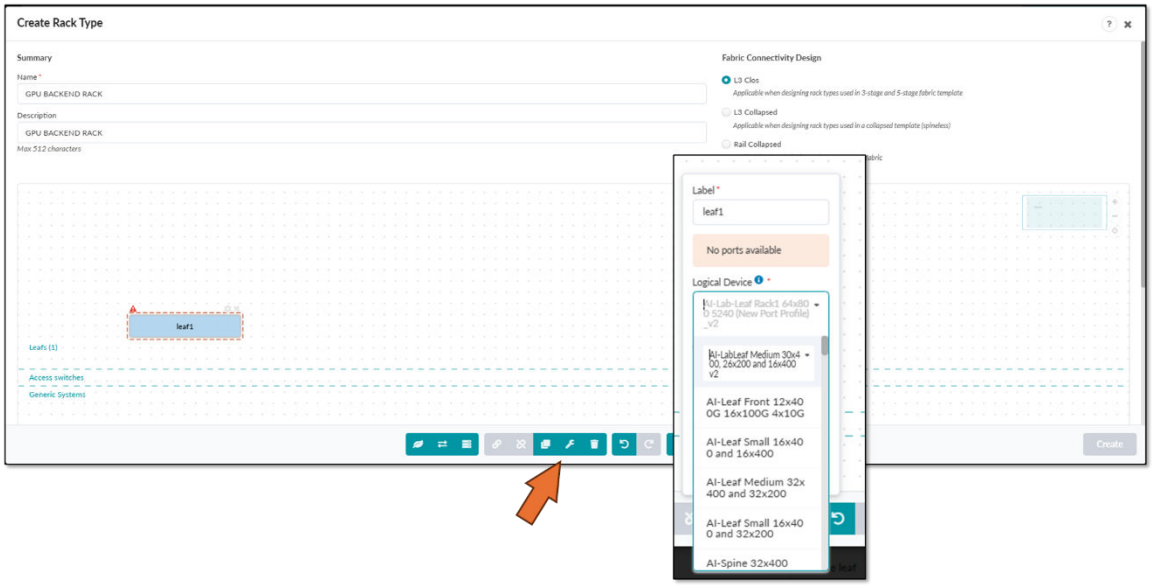
4. Create the first leaf by clicking on the Add leaf button.

Figure 61: Creating Leaf nodes

Select the switch that was created and click on Manage properties of selected node(s).

Select the appropriate Logical Device.

Figure 62: Configure Leaf nodes properties



5. Create additional leaf nodes by cloning the leaf created in the previous step. Repeat until 8 leaf total have been added.

Figure 62: Creating additional leaf nodes by cloning the leaf node

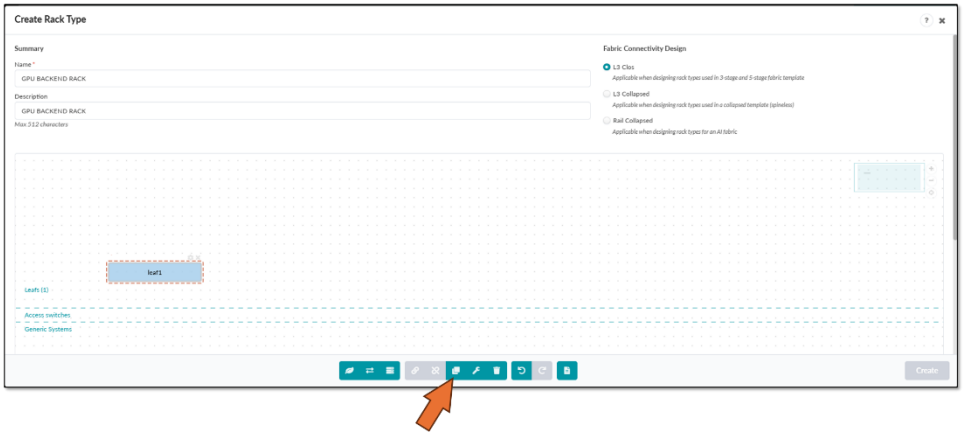


Figure 63: Additional leaf nodes created

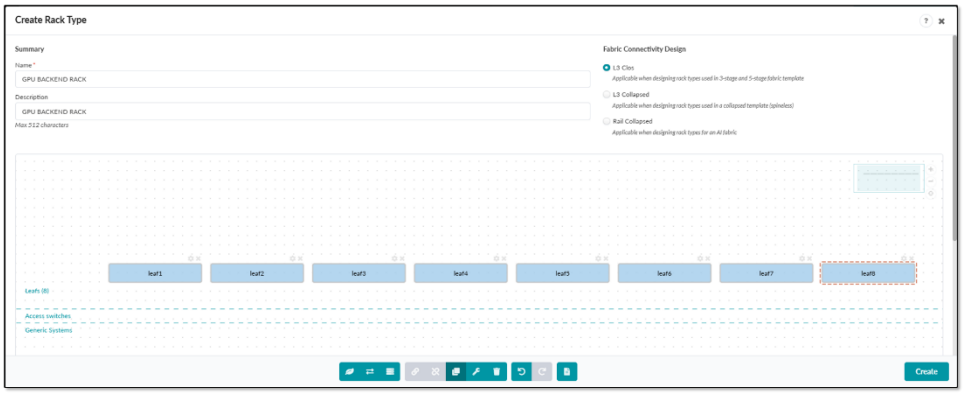


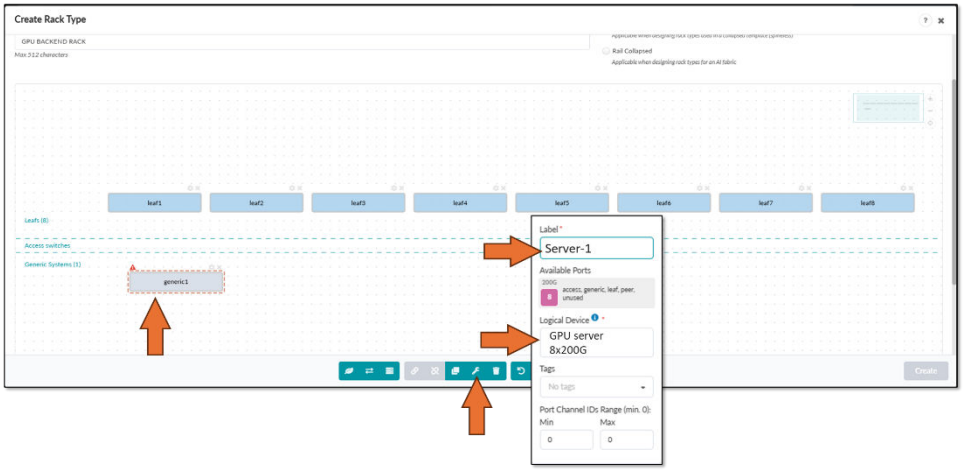
6. Create the first GPU server (generic systems) by clicking on Add generic system

Figure 64: Cloning leaf nodes.

Select the server that was created and click on Manage properties of selected node(s).

Provide a name for the server and select the appropriate Logical Device.

Figure 65: Creating and configuring first GPU server (generic system)



7. Create GPU server to Leaf node connections.

Select the Server and the first leaf and click on Manage Links.

Make sure the box “Is a Part of the Rail” is checked.

Repeat until all connections between the server and all the leaf nodes have been created.

Figure 66: Creating connections between GPU servers and leaf nodes

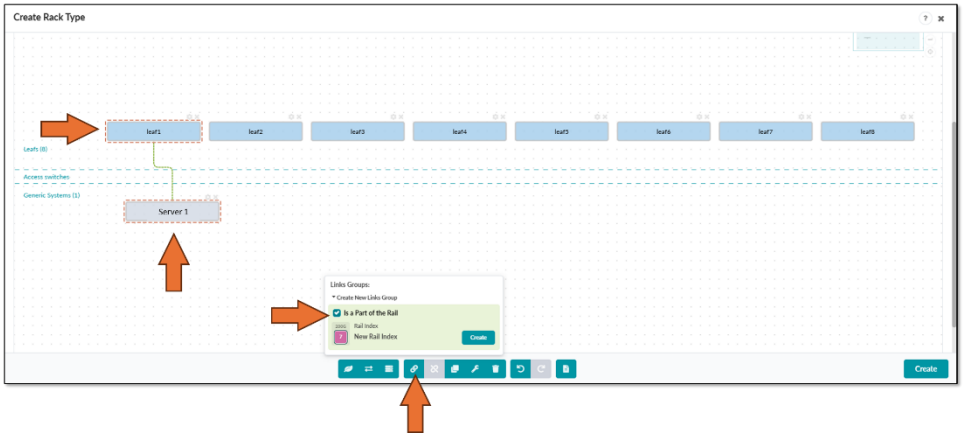


Figure 67: Creating connections between GPU servers and leaf nodes

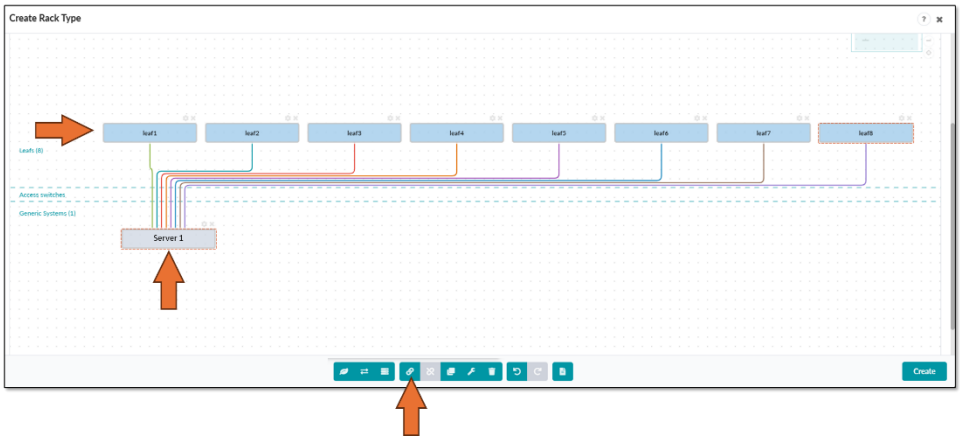

8. Create additional servers by cloning the server created in the previous step. Repeat until 8 leaf total have been added. All connections will be cloned.

Figure 68: Creating additional servers

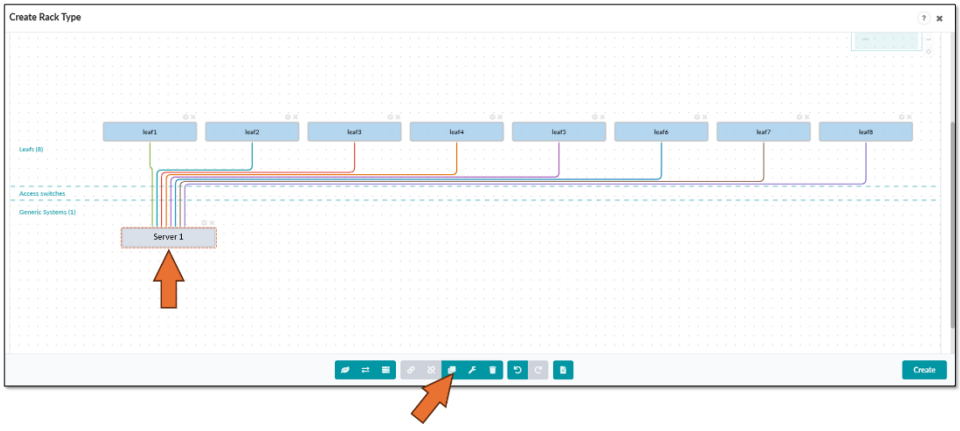

Figure 69: Creating additional servers

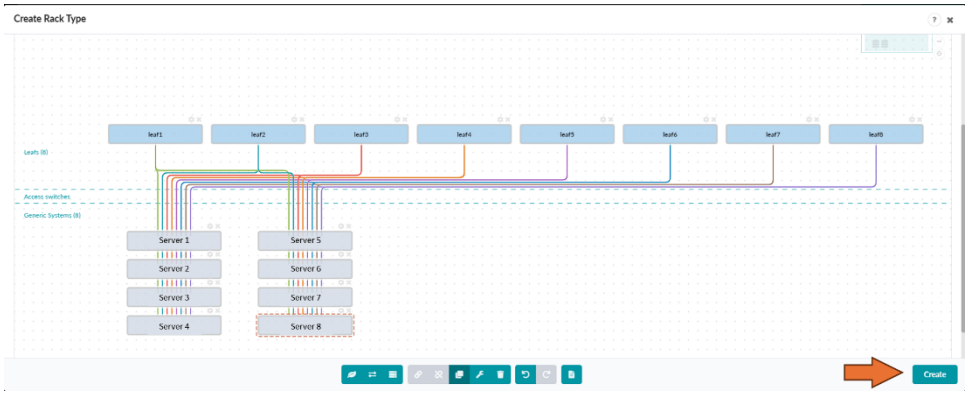

9. Verify the Rack has been created correctly:

Figure 70: Creating connections between GPU servers and leaf nodes

Figure 71: Creating connections between GPU servers and leaf nodes

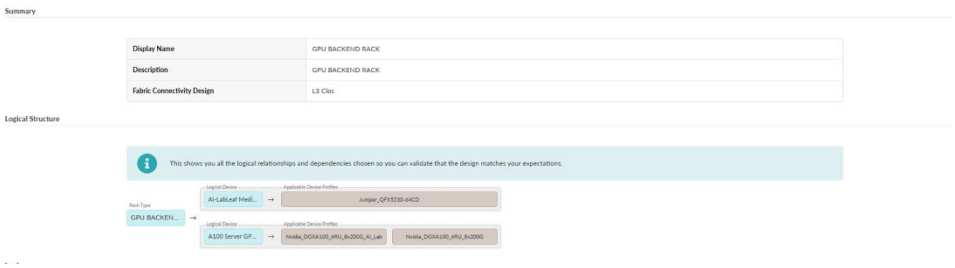

Figure 72: Creating connections between GPU servers and leaf nodes

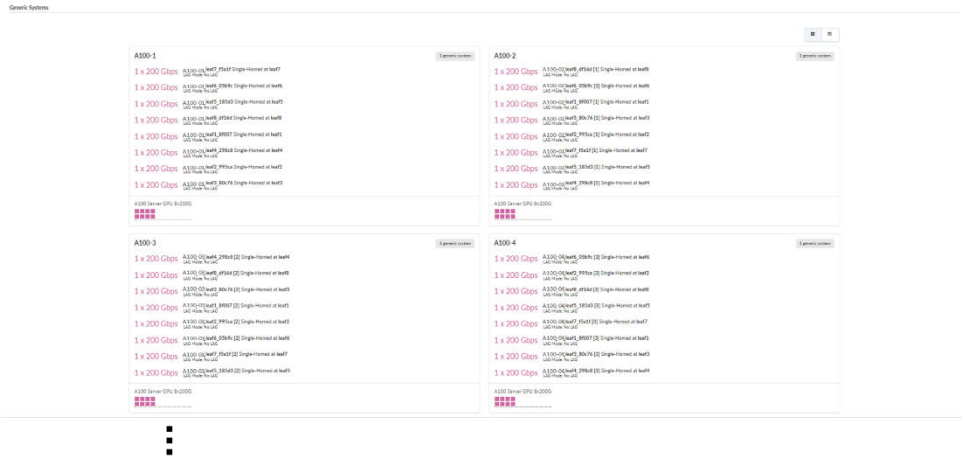
Figure 73: Creating connections between GPU servers and leaf nodes



Step 4: Create a Template.

Navigate to **Design** -> **Templates** -> **Create Template**

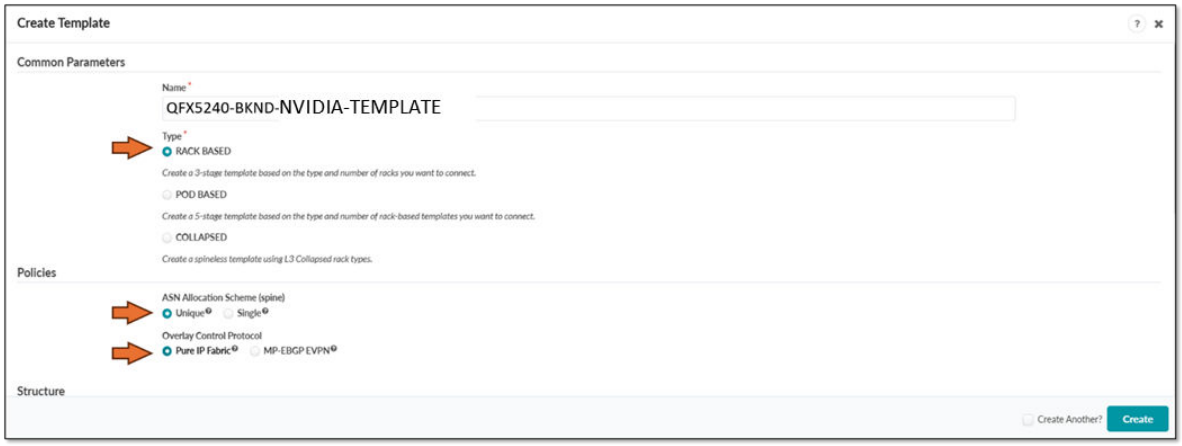
1. Click on **Create Template**

   Figure 74: Create Apstra Template

   NOTE: You can choose between **Create Template** or **Create AI Cluster Template** (Select from pre-existing designs based on required number of GPUs per stripe, and number of stripes.). We will demonstrate the **Create Template** option here.

2. Enter the name of the template, and select Type RACK BASED, policies ASN allocation Unique, and Overlay Pure IP Fabric.

   Figure 75: Creating a Template in Apstra - Parameters



3. Scroll down and select the Rack type and Spine logical device created in previous steps, set the number of Racks (which is equivalent to saying number of stripes), and the number of spines. Click on create when ready, as shown in Figure 75.

Figure 76: Creating a Template in Apstra - Structure

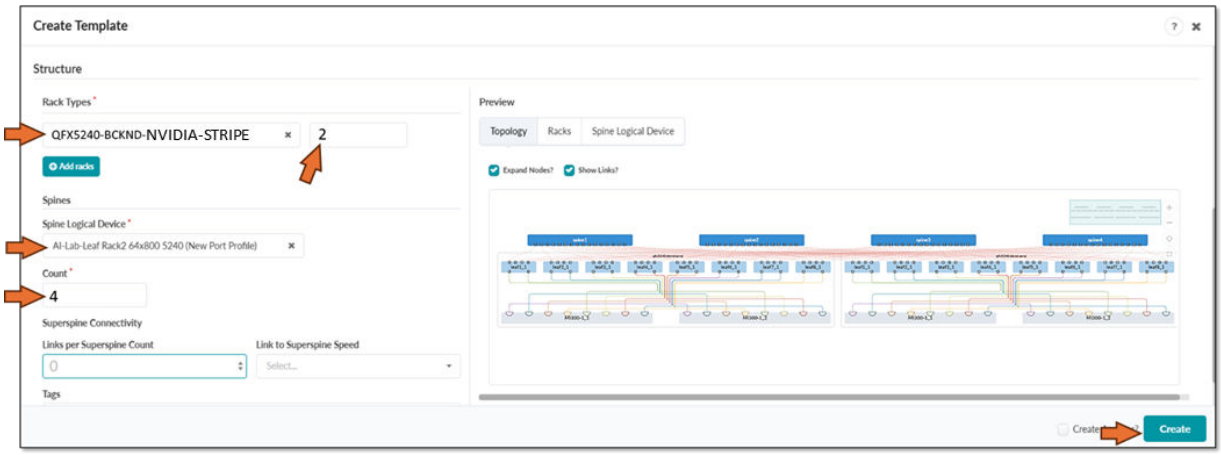


Figure 77: Verifying new template creation

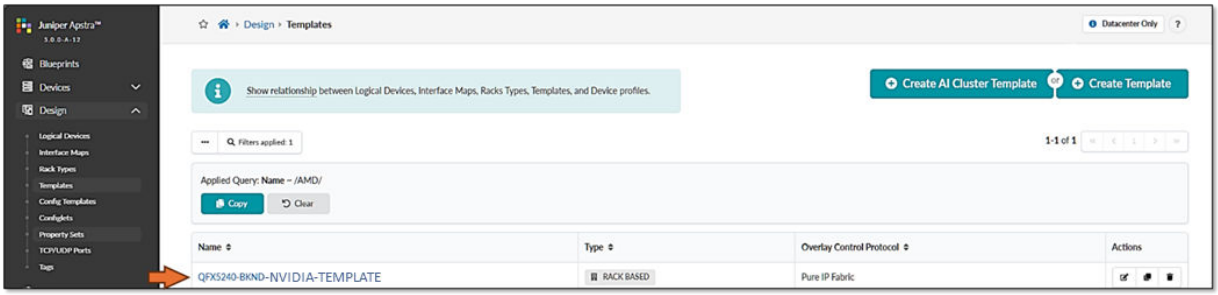
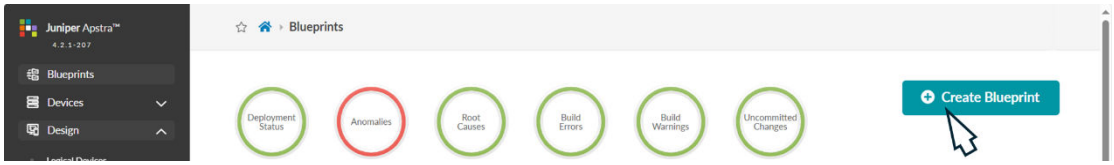


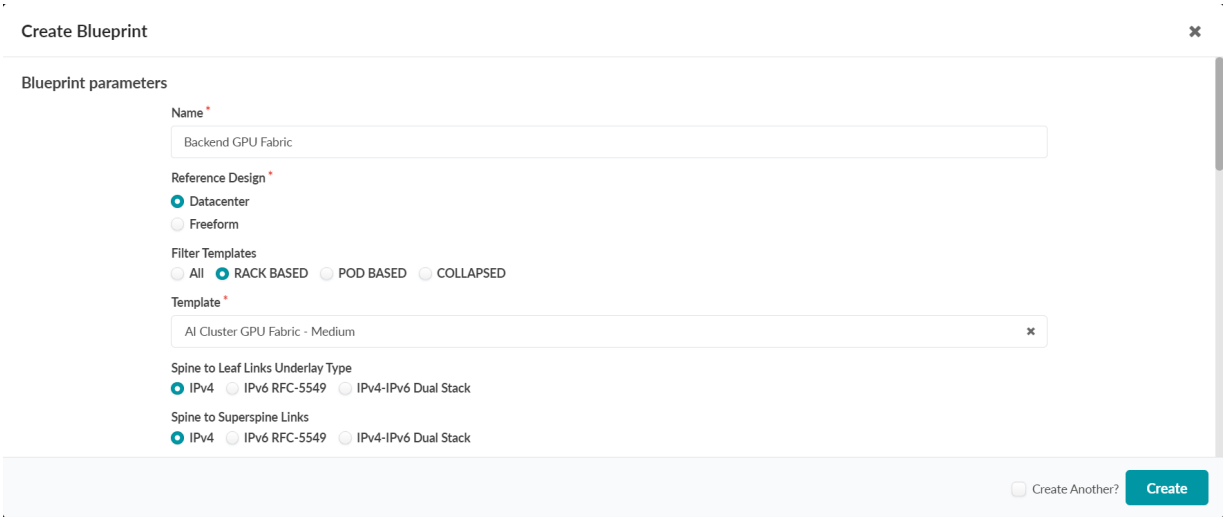
Step 5. Create the GPU Backend Fabric Blueprint

1. Navigate to the **Blueprints** section and click on **Create Blueprint,** as shown in Figure 78.
   Figure 78: Creating a Blueprint in Apstra



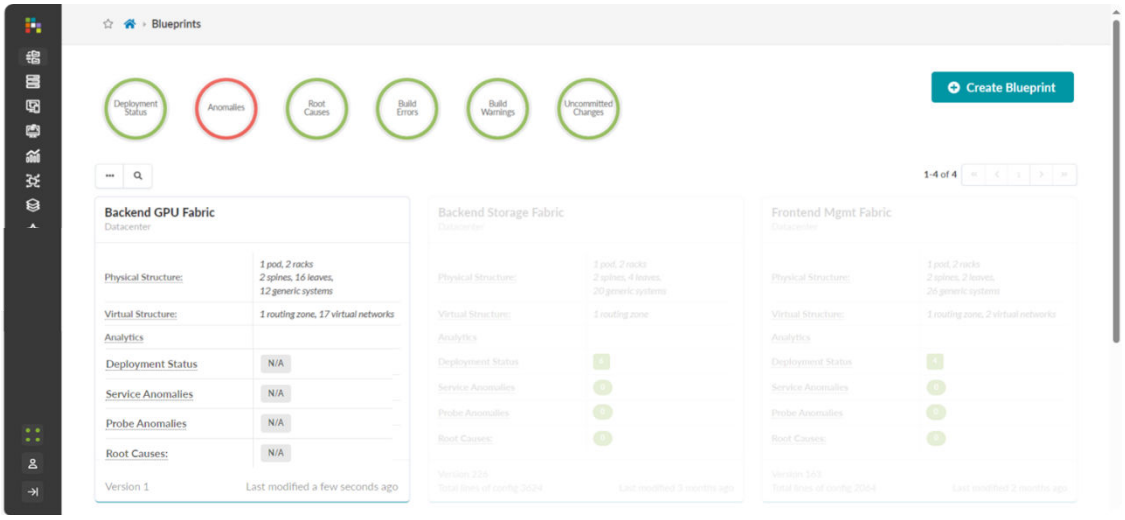
2. Provide a name for the new blueprint, select data center as the reference design, and select Rack-based. Then select the template that was created in the previous step, which will include the two rack types that were created before.

Figure 79: New Blueprint Attributes in Apstra



Once the blueprint is successfully initiated by Apstra, it will be included in the Blueprint dashboard as shown below.

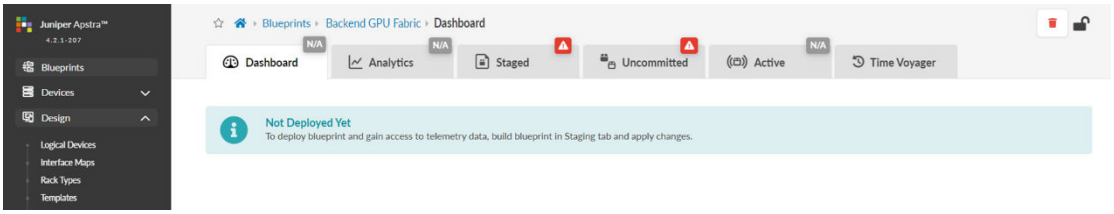
Figure 80: New Blueprint Added to Blueprint Dashboard



Notice that the Deployment Status, Service Anomalies, Probe Anomalies and Root Causes all shown as N/A. This is because you will need to complete additional steps that inlcudes mapping the different roles in the blueprint to the physical devices, defining which interfaces will be used, etc.

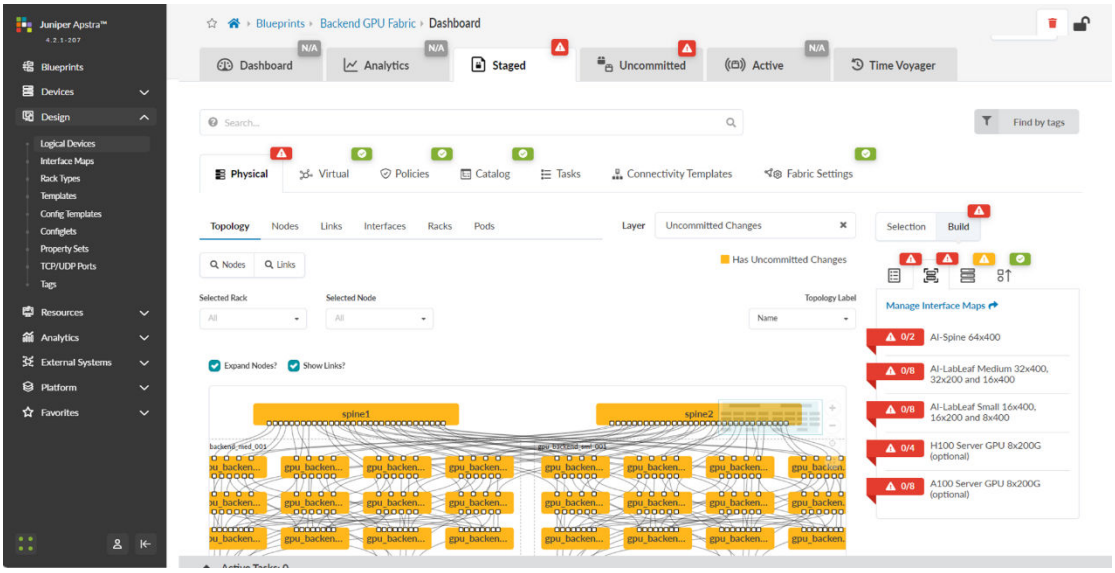
When you click on the blueprint name and enter the blueprint dashboard it will indicate that the blueprint has not been deployed yet.

Figure 81: New Blueprint's dashboard



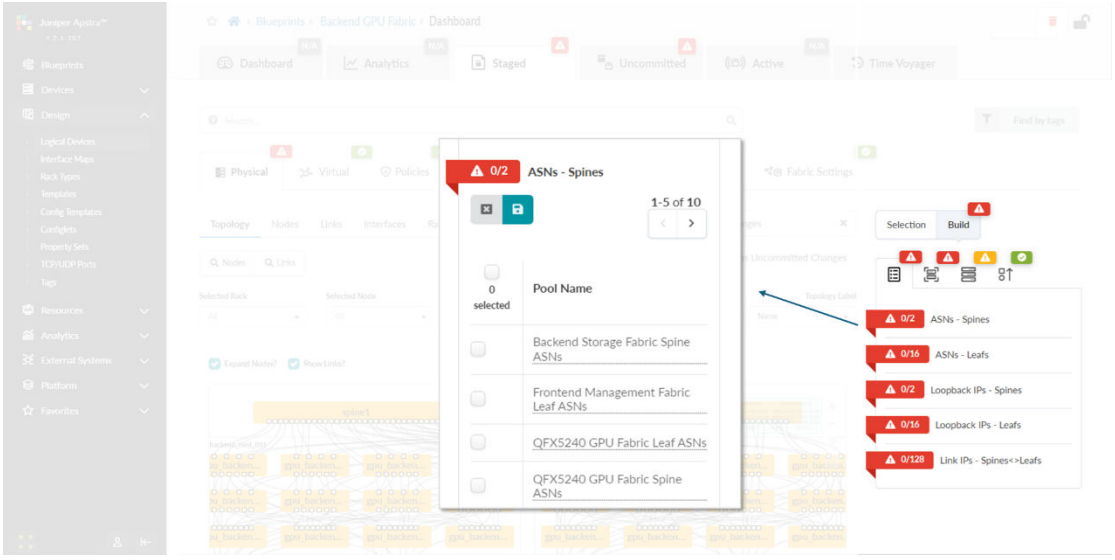
The Staged view as depicted in Figure 82 shows that the topology is correct, but attributes such as mandatory ASNs and loopback addressing for the spines and the leaf nodes, and the spine to leaf links addressing must be provided by the user.

Figure 82: Undeployed Blueprint Dashboard



You will need to edit each one of these attributes and select from predefined pools of addresses and ASNs, as shown in the example on Figure 83, to fix this issue.

Figure 83: Selecting ASN Pool for Spine Nodes



You will also need to select Interface Maps for each devices' role and along with assignment of system IDs as shown in Figures 84-85.

Figure 84: Mapping Interface Maps to Spine Nodes

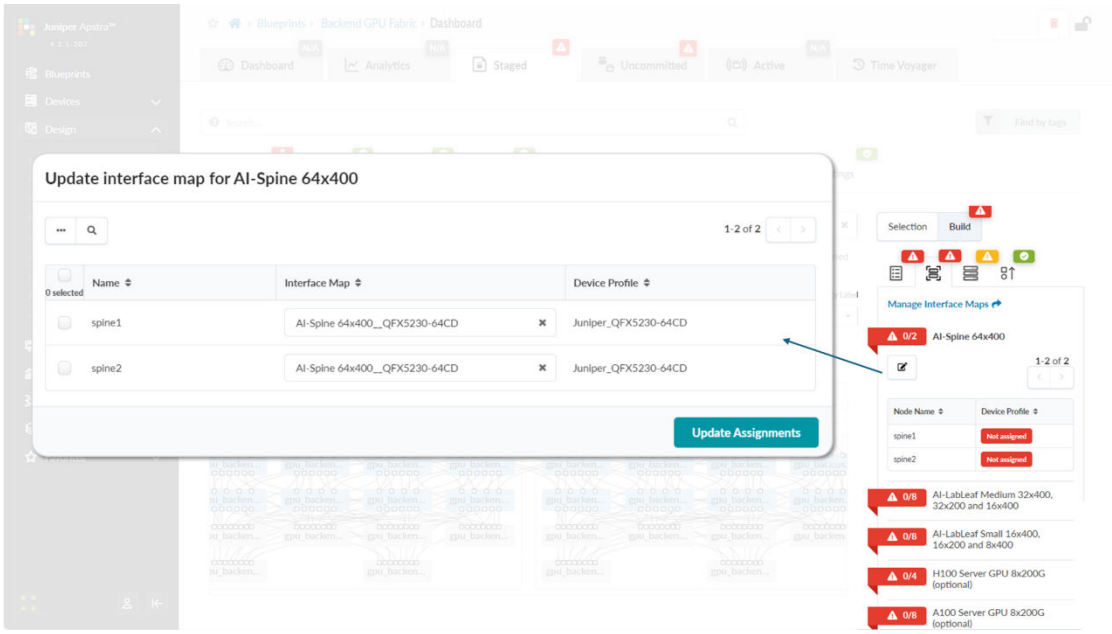


Figure 85: Mapping Spine Nodes to Physical Devices (System IDs)

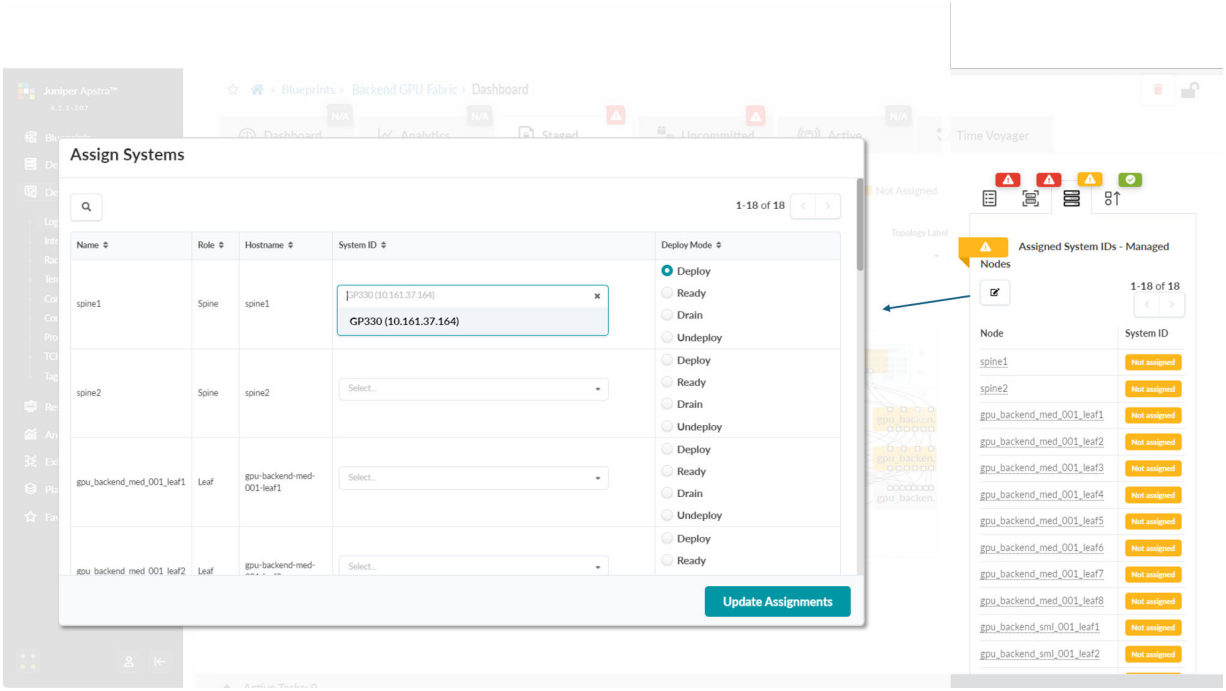
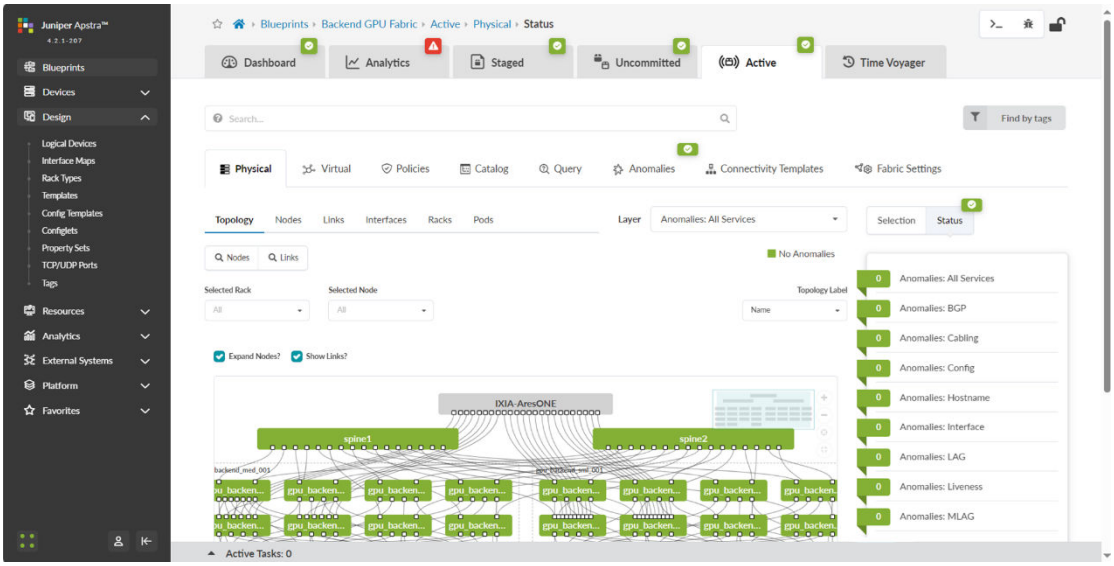


Once all these steps are completed, you can commit all the changes and Apstra will generate and push all the necessary vendor-specific configuration to the nodes. Once this has been completed, you should be able to view an active blueprint that represents the successfully deployed fabric as shown in Figure 86.

Figure 86: Mapping Spine Nodes to Physical Devices 2 (System IDs)



Step 6: Create Configlets for DCQCN and DLB.

In the Apstra version used for this JVD, features such as ECN, PFC (DCQCN), and DLB are not natively available. Therefore, Apstra configlets should be used to add these features to the configurations before they are deployed to the fabric devices.

The configlet used for the DCQCN and DLB features on the QFX leaf nodes is as follows:

- ```
  /* DLB configuration for Thor NIC2 Adapter */

  hash-key {

      family inet {

          layer-3;

          layer-4;

      }

  }

  enhanced-hash-key {

      ecmp-dlb {

          flowlet {
  ```
  ```

```
            inactivity-interval 128;
            flowset-table-size 2048;
        }
        ether-type {
            ipv4;
            ipv6;
        }
        sampling-rate 1000000;
    }
}
protocols {
    bgp {
        global-load-balancing {
            load-balancer-only;
        }
    }
}
/* DCQCN configuration */
classifiers {
    dscp mydscp {
        forwarding-class CNP {
            loss-priority low code-points 110000;
```

```
        }
        forwarding-class NO-LOSS {
            loss-priority low code-points 011010;
        }
    }
}
drop-profiles {
    dp1 {
        interpolate {
            fill-level [ 55 90 ];
            drop-probability [ 0 100 ];
        }
    }
}
    shared-buffer {
        ingress {
       buffer-partition lossless {
          percent 66;
          dynamic-threshold 10;
       }
       buffer-partition lossless-headroom {
```

```
           percent 24;
        }
        buffer-partition lossy {
           percent 10;
        }
      }
      egress {
        buffer-partition lossless {
           percent 66;
        }
        buffer-partition lossy {
           percent 10;
        }
      }
    }
forwarding-classes {
    class CNP queue-num 3;
    class NO-LOSS queue-num 4 no-loss pfc-priority 3;
}
congestion-notification-profile {
    cnp {
        input {
```

```
            dscp {
                code-point 011010 {
                    pfc;
                }
            }
        }
        output {
            ieee-802.1 {
                code-point 011 {
                    flow-control-queue 4;
                }
            }
        }
    }
}
interfaces {
    et-* {
        congestion-notification-profile cnp;
        scheduler-map sm1;
        unit * {
            classifiers {
```

```
                dscp mydscp;

            }

        }

    }

}

scheduler-maps {

    sm1 {

        forwarding-class CNP scheduler s2-cnp;

        forwarding-class NO-LOSS scheduler s1;

    }

}

schedulers {

    s1 {

        drop-profile-map loss-priority any protocol any drop-profile dp1;

        explicit-congestion-notification;

    }

    s2-cnp {

        transmit-rate percent 5;

        priority strict-high;

    }

}
```

The configlet used for the DCQCN and DLB features on the QFX spine nodes is as follows:

- ```
  /* DLB configuration */
  hash-key {
      family inet {
          layer-3;
          layer-4;
      }
  }
  enhanced-hash-key {
      ecmp-dlb {
          flowlet {
              inactivity-interval 128;
              flowset-table-size 2048;
          }
          ether-type {
              ipv4;
              ipv6;
          }
          sampling-rate 1000000;
      }
  }
  ```
  ```

```
protocols {
    bgp {
        global-load-balancing {
            helper-only;
        }
    }
}
/* DCQCN configuration */
class-of-service {

            priority strict-high;
        }
    }
}
```

The configuration used for the DCQCN features on the PTX10008 as spine devices is as follows:

NOTE: when PTX10008 is used as a spine node, GLB is not an option.

- ```
  /* ALB configuration */
  policy-options {
      policy-statement ALB-TEST {
          term 1 {
              from {
                  route-filter 10.200.1.0/24 exact;
              }
  ```
  ```

```
            then {
                load-balance adaptive;
            }
        }
    }
}
routing-options {
    forwarding-table {
        export ALB-TEST;
    }
}

}
```

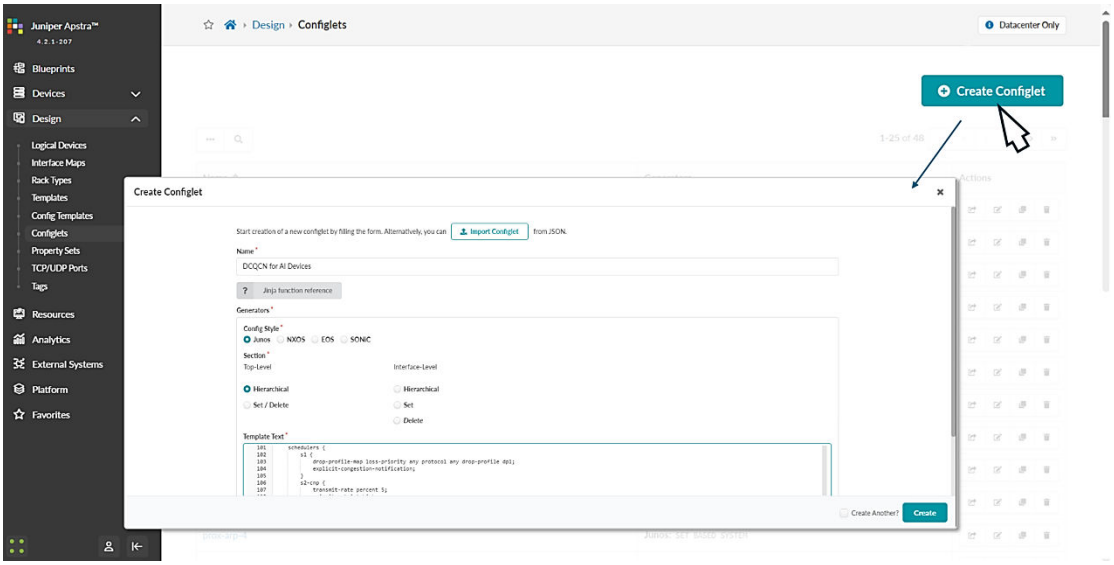
To create these configlets:

1. Navigate to **Design** -> **Configlets** -> **Create Configlet** and click on **Create configlet**.
2. Provide a name for the configlet, select the operating system, vendor and configuration mode and paste the above configuration snippet on the template text box as shown below:

Figure 87: DCQCN Configlet Creation in Apstra



Terraform Automation of Apstra for the AI Fabric

IN THIS SECTION

AI Terraform Configs

Juniper has compiled a set of Terraform configs to help set up data center fabrics for an AI cluster. AI training requires a dedicated GPU Backend fabric, a dedicated Storage Backend fabric, and a Frontend fabric. Here we show such Apstra-managed network fabrics deploying logical devices, racks and templates for DGX (or HGX equivalent) servers based on A100 and H100 GPUs having 200GE and 400GE access connectivity respectively. The logical devices, racks, and templates defined here create the NVIDIA Rail-optimized topology.

The GitHub repository for AI designs using Apstra can be found:

https://github.com/Juniper/terraform-apstra-examples/tree/master/ai-cluster-designs/

AI JVD Specific Terraform Configs

Based on the AI cluster designs with rail-optimized GPU fabrics of various sizes, this Terraform config for Apstra will build a set of 3 blueprints for a reference AI cluster's dedicated GPU Backend fabric, a dedicated Storage Backend fabric, and a Frontend fabric.

This example shall serve as a Juniper Validated Design (JVD) set of configurations that can be applied to larger clusters. It has two NVIDIA rail-optimized groups with Juniper QFX5220 leaf switches in one stripe of 8 and QFX5230 leaf switches in another stripe of 8. It has options for both QFX5230 spines or high-radix PTX10008 spines, with examples here for A100s and H100-based servers in uniform racks or as deployed in the "Lab Leaf" rack with mixed server access for half A100 and half H100 connectivity to serve as an example, and because that is what is used in the real lab test environment for this configuration.

The GitHub repository for this specific AI JVD can be found:

https://github.com/Juniper/terraform-apstra-examples/tree/master/ai-cluster-jvd/

NVIDIA Configuration

IN THIS SECTION

NVIDIA® ConnectX® family of network interface cards (NICs) offer advanced hardware offload and acceleration features, and speeds up to 400G, supporting both Ethernet and Infiniband protocols.

Always refer to the official manufacturer documentation when making changes. This section provides some guidelines based on the AI JVD lab testing.

Converting NVIDIA ConnectX NICs from Infiniband to Ethernet

By default, the NVIDIA ConnectX NICs are set to operate as Infiniband interfaces and must be converted to Ethernet using the mlxconfig tool.

1) Check the status of the ConnectX NICs using sudo mst status.

NOTE: Mellanox Software Tools (MST) is part of the Mellanox firmware tools suite and can be used to manage and interact with Mellanox network adapters.

- ```
  user@A100-01:/dev/mst$ sudo mst -h

  Usage:

      /usr/bin/mst {start|stop|status|remote|server|restart|save|load|rm|add|help|version|
  gearbox|cable} Type "/usr/bin/mst help" for detailed help

  user@A100-01:/dev/mst$ sudo mst status | egrep "module|load"

  MST modules:

      MST PCI module loaded

      MST PCI configuration module loaded
  ```

Start the mst service or load the mst modules if necessary.

Example:

- ```
  user@H100-01:~$ sudo mst start

  Starting MST (Mellanox Software Tools) driver set

  Loading MST PCI module - Success

  [warn] mst_pciconf is already loaded, skipping

  Create devices

  Unloading MST PCI module (unused) - Success

  user@A100-01:~/scripts$ sudo mst status

  MST modules:

  ------------

      MST PCI module is not loaded
  ```

```
    MST PCI configuration module loaded
```

The example shows “MST PCI module is **not loaded”.** To load it, use the command

```
modprobe
mst_pci.
```

- ```
  user@A100-01:/dev/mst$ sudo modprobe mst_pci

  user@A100-01:/dev/mst$ sudo mst status

  MST modules:

  ------------

      MST PCI module loaded

      MST PCI configuration module loaded
  ```

2) Identify the interface that you want to convert,

This **sudo mst status -v** command will provide a list of Mellanox devices (ConnectX-6 and ConnectX-7 NICs) detected on the system, along with their type, Mellanox device name, PCI addresses, RDMA interface name, NET interface name, and NUMA ID, as shown in the example below:

- ```
  user@A100-01:/dev/mst$ sudo mst status -v

  MST modules:

  ------------

      MST PCI module loaded

      MST PCI configuration module loaded

  PCI devices:

  ------------

  DEVICE_TYPE         MST                           PCI       RDMA     NET                 NUMA
  ```

```
ConnectX7(rev:0)    /dev/mst/mt4129_pciconf7.1  cb:00.1  mlx5_13  net-eth13          1

ConnectX6(rev:0)    /dev/mst/mt4123_pciconf0.1  a9:00.1  mlx5_15  net-eth15          1

ConnectX6(rev:0)    /dev/mst/mt4123_pciconf0    a9:00.0  mlx5_14  net-weka_eth       1

Cable devices:
```

```
---------------

mt4129_pciconf7_cable_0

mt4129_pciconf6_cable_0

mt4129_pciconf5_cable_0

mt4129_pciconf4_cable_0

mt4129_pciconf3_cable_0

mt4129_pciconf2_cable_0

mt4129_pciconf1_cable_0

mt4129_pciconf0_cable_0

mt4125_pciconf0_cable_0

mt4123_pciconf0_cable_0
```

For the first interface in the list, you can identify the following:

- Type = **ConnectX7(rev:0)**
- Mellanox device name = **mt4129_pciconf7 (/dev/mst/mt4129_pciconf7)**
- PCI addresses = **cb:00.0**
- RDMA interface name = **mlx5_12**
- NET interface name = **net-gpu6_eth**
- NUMA = **1**

Notice that for some of the interfaces the name follows the standard Linux interface naming scheme (e.g. net-enp14s0f1np1), while others do not (e.g. net-gpu0_eth). The interface names that do not follow the standard are user defined names for easy identification purposes. That means the default name was changed in the /etc/netplan/. We will show an example of how to do this later in this section.

3) Identify what mode a given interface is running using

mlxconfig -d <device> query

Example:

- ```
  user@A100-01:~/scripts$ sudo mlxconfig -d /dev/mst/mt4129_pciconf7query | grep LINK_TYPE

          LINK_TYPE_P1     IB(1)

          LINK_TYPE_P2     IB(1)  <= indicates link is operating in Infiniband mode
  ```

Notice that you need to use the Mellanox device name, including the path (/dev/mst/mt4129_pciconf7). Also, LINK_TYPE_P1 and LINK_TYPE_P2 refer to the two physical ports in a dual-port Mellanox adapter.

4) If an interface is operating in Infiniband mode, you can change the mode for ethernet mode using

mlxconfig -d <device> set [LINK_TYPE_P1=<link_type>] [LINK_TYPE_P2=<link_type>]

Example

- ```
  user@A100-01:~/scripts$ sudo mlxconfig -d /dev/mst/mt4129_pciconf7 set LINK_TYPE_P1=2
  LINK_TYPE_P2=2

  Device #1:

  ----------

  Device type:        ConnectX7

  Name:               MCX755106AS-HEA_Ax

  Description:        NVIDIA ConnectX-7 HHHL Adapter Card; 200GbE (default mode) / NDR200 IB;
  Dual-port QSFP112; PCIe 5.0 x16 with x16 PCIe extension option; Crypto Disabled; Secure Boot
  Enabled

  Device:             /dev/mst/mt4129_pciconf7

  Configurations:                                          Next Boot       New

          LINK_TYPE_P1                                ETH(2)              ETH(2)

          LINK_TYPE_P2                                ETH(2)              ETH(2)

   Apply new Configuration? (y/n) [n] : y

  Applying... Done!
  ```

```
-I- Please reboot machine to load new configurations.

user@A100-01:~/scripts$ sudo mlxconfig -d /dev/mst/mt4129_pciconf7query | grep LINK_TYPE

        LINK_TYPE_P1     ETH(2)

        LINK_TYPE_P2     ETH(2)   <= indicates link is operating in Ethernet mode
```

Again, notice that you need to use the Mellanox device name, including the path (/dev/mst/mt4129_pciconf7).

NOTE: Changes via mlxconfig require the box to be power cycled.

To check the status of the interface you can use the mlxlink:

- ```
  user@A100-01:/dev/mst$ sudo mlxlink -d /dev/mst/mt4129_pciconf4

HowTo Find Mellanox Adapter Type and Firmware/Driver version (Linux) (nvidia.com)

Firmware Support and Downloads - Identifying Adapter Cards (nvidia.com)

Identifying NICs and GPUs Mappings and Assigning the Appropriate Interface Name

NICs can be used by any GPU at any time; it is not hard coded that a given GPU can only communicate with the outside world using a specific NIC card. However, there are preferred communication paths between GPUs and NICs, which in some cases could be seen as a 1:1 correspondence between them. This will be shown in the steps below.

NCCL (NVIDIA Collective Communications Library) will choose the path that has the best connection from a given GPU to one of the NICs.

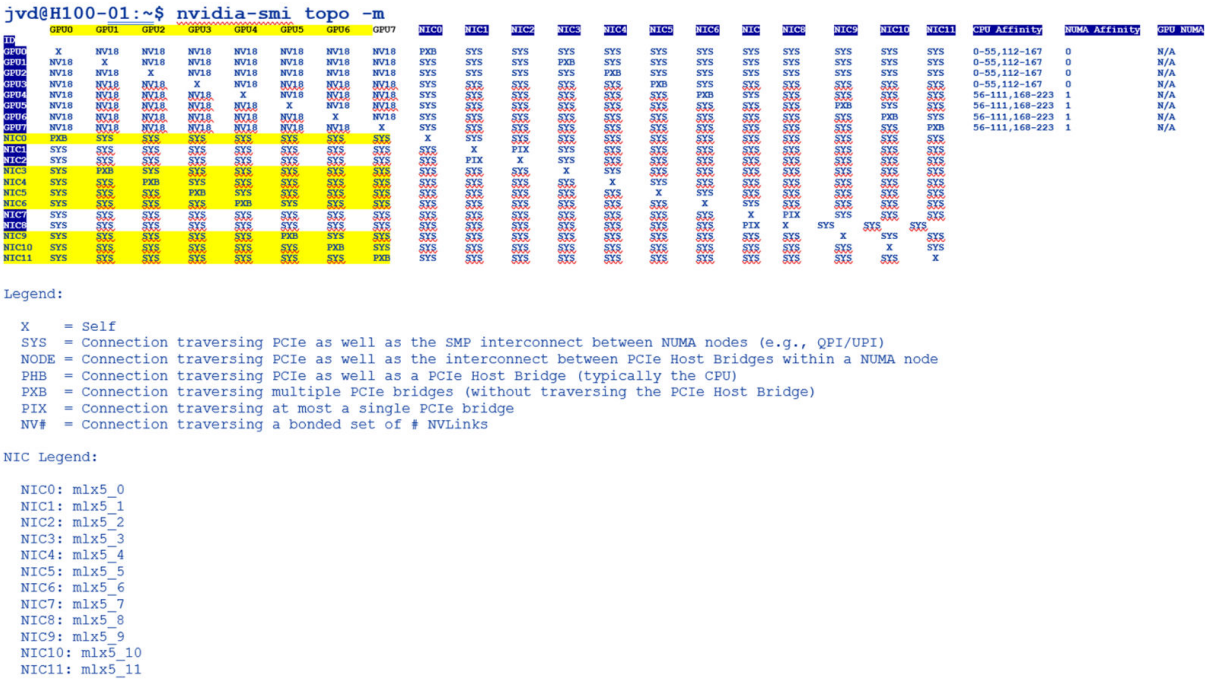
To identify the paths selected by NCCL and what the best path between a GPU and a NIC is, follow these steps:

Use the nvidia-smi topo -m command, which displays topological information about the system, to identify the connection type between GPUs and NICs:

EXAMPLES:

- *DGX H100:*

Figure 92. Nvidia H100 System Management Interface (SMI) system topology information



System Management Interface SMI | NVIDIA Developer

Based on our research:

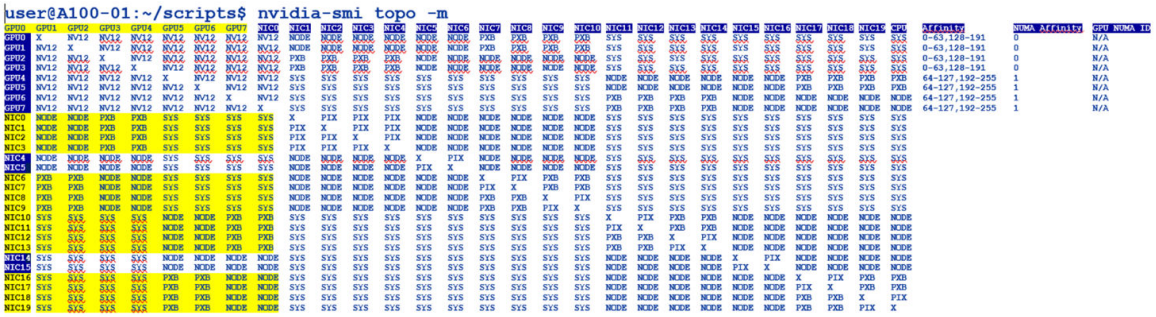
Table 26: Performance per connection type

Connection Type	Description	Performance
PIX	PCIe on the same switch	Good
PXB	PCIe through multiple switches, but not host bridge	Good
PHB	PCIe switch and across a host bridge on the same NUMA - uses CPU	OK

NODE	PCIe switch and across multiple host bridge on the same NUMA	Bad
SYS	PCIe switch and across QPI/UPI bus between NUMA nodes - uses CPU	Very Bad
NV#	NVLink	Very Good

- *HGX A100:*

Figure 93. Nvidia A100 System Management Interface (SMI) system topology information



Identify PBX Connections

If you focus on the highlighted sections of the nvidia-smi output, you can see that for each GPU there is one or more NIC connection(s) of type **PXB**. This is the preferred "direct" path from each GPU to a given NIC. That means, when the GPU needs to communicate to a remote device, it will use one of these specific NICs, as the first option.

- *DGX H100:*

Introduction to NVIDIA DGX H100/H200 Systems — NVIDIA DGX H100/H200 User Guide 1 documentation

Changing a NIC's Interface Name, and Assign IP Addresses and Routes

NIC attributes such as the IP address or the interface name can be made by editing and reapplying to the netplan.

The network configuration is described in the file: /etc/netplan/01-netcfg.yaml as shown in the example table below. Any attribute changes involve editing this file and reapplying the network plan as will be shown in the examples later in this section.

Table 29: Nvidia HGX A100 interface configuration example:

netcfg.yaml output		
jvd@A100-01:/etc/netplan$ more 01-netcfg.yaml		
# This is the network config written by 'subiquity'	**gpu0_eth:**	**gpu4_eth:**

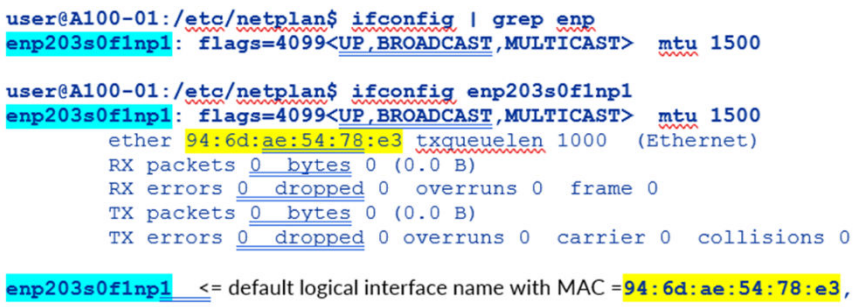
Mapping an Interface Name to a Specific NIC (Physical Interface)

Map the interface name to the MAC of the physical interface in the configuration file:

Figure 99. Nvidia A100 physical interface identification example



where:

en = ethernet network interface.

p203s0 = physical location of the network interface.

203 bus number.

s0 = slot number 0 on the bus.

f1 = function number 1 for the network interface.

np1 = Network Port 1

```
enp4s10f1                          pci 0000:04:0a.1
| | | |                                 |  |  | |
| | | |                   domain <- 0000  |  | |
| | | |                                   |  | |
en| | |  --> ethernet                     |  | |
  | | |                                   |  | |
  p4| |  --> prefix/bus number (4)   <-- 04  | |
    | |                                      | |
    s10|  --> slot/device number (10) <--    10 |
       |                                        |
       f1 --> function number (1)     <--       1
```

Function 0: Might be the primary Ethernet interface.

Function 1: Might be a second Ethernet interface.

Function 2: Might be a management or diagnostics interface.

Figure 100. Nvidia A100 netplan file modification example

```
user@A100-01:/etc/netplan$ vi 01-netcfg.yaml
---more---
new_interface:
      match:
        macaddress: 94:6d:ae:54:78:e3

```

Apply the changes using the netplan apply command

Figure 101. Nvidia A100 netplan application example

```
user@A100-01:/etc/netplan$ sudo ip link set dev enp203s0f1np1 down

user@A100-01:/etc/netplan$ ifconfig enp203s0f1np1
enp203s0f1np1: error fetching interface information: Device not found

user@A100-01:/etc/netplan$ sudo netplan apply

user@A100-01:/etc/netplan$ ifconfig new_iface_name
new_iface_name: flags=4099<UP,BROADCAST,MULTICAST>  mtu 9000
        ether 94:6d:ae:54:78:e3  txqueuelen 1000  (Ethernet)
        RX packets 0  bytes 0 (0.0 B)
        RX errors 0  dropped 0  overruns 0  frame 0
        TX packets 0  bytes 0 (0.0 B)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

Changing the NIC Name

Change the value of set-name in the configuration file and save the changes:

Figure 102. Nvidia A100 netplan interface name change example

```
jvd@A100-01:/etc/netplan$ ifconfig gpu0_eth  <= current name
gpu0_eth: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 9000
        inet 10.200.0.8  netmask 255.255.255.0  broadcast 10.200.0.255
        inet6 fe80::966d:aeff:fe54:7222  prefixlen 64  scopeid 0x20<link>
        ether 94:6d:ae:54:72:22  txqueuelen 1000  (Ethernet)
        RX packets 2079477652  bytes 17618315023885 (17.6 TB)
        RX errors 0  dropped 8  overruns 0  frame 0
        TX packets 2082335255  bytes 17741532549214 (17.7 TB)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

jvd@A100-01:/etc/netplan$ vi 01-netcfg.yaml
 ---more---
    gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:
        - 10.200.0.8/24
      routes:
        - to: 10.200.0.0/16
          via: 10.200.0.254
          from: 10.200.0.8
            set-name: gpu0_eth   <= current name

jvd@A100-01:/etc/netplan$ cat 01-netcfg.yaml
 ---more---
    gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:

      routes:
        - to: 10.200.0.0/16
          via: 10.200.0.254
          from: 10.200.0.8
            set-name: gpu0_eth0   <= new name
:wq
```

Apply the Changes Using the netplan apply command

Figure 103. Nvidia A100 netplan interface name change application and verification example

Figure 45. Nvidia A100 netplan interface name change application and verification example

```
user@A100-01:/etc/netplan$ sudo netplan apply

user@A100-01:/etc/netplan$ ifconfig gpu0_eth0     <= new name
gpu0_eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 9000
        inet 10.200.0.8  netmask 255.255.255.0  broadcast 10.200.0.255
        inet6 fe80::966d:aeff:fe54:7222  prefixlen 64  scopeid 0x20<link>
        ether 94:6d:ae:54:72:22  txqueuelen 1000  (Ethernet)
        RX packets 2079477704  bytes 17618315028610 (17.6 TB)
        RX errors 0  dropped 8  overruns 0  frame 0
        TX packets 2082335268  bytes 17741532551122 (17.7 TB)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

To Change the Current IP Address or Assign an IP Address to the NIC

Change or add the address under the proper interface in the configuration file, and save the changes:

Figure 104. Nvidia A100 netplan interface IP address change example

```
user@A100-01:/etc/netplan$ ifconfig gpu0_eth
gpu0_eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 9000
    inet 10.200.0.8  netmask 255.255.255.0  broadcast 10.200.0.255 <= current IP address
    inet6 fe80::966d:aeff:fe54:7222  prefixlen 64  scopeid 0x20<link>
    ether 94:6d:ae:54:72:22  txqueuelen 1000  (Ethernet)
    RX packets 2079477704  bytes 17618315028610 (17.6 TB)
    RX errors 0  dropped 8  overruns 0  frame 0
    TX packets 2082335268  bytes 17741532551122 (17.7 TB)
    TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

user@A100-01:/etc/netplan$ vi 01-netcfg.yaml
---more---
   gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:
        - 10.200.0.8/24 <= current IP address

user@A100-01:/etc/netplan$ vi 01-netcfg.yaml
---more---
   gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:
        - 10.200.0.18/24        <= new IP address
:wq
```

Enter the IP addresses preceded with a hyphen and indented; make sure to add the subnet mask.

Apply the Changes Using the netplan apply Command

Figure 105. Nvidia A100 netplan interface new IP address application and verification example

```
user@A100-01:/etc/netplan$ sudo netplan apply

user@A100-01:/etc/netplan$ ifconfig gpu0_eth
gpu0_eth: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 9000
      inet 10.200.0.18  netmask 255.255.255.0  broadcast 10.200.0.255 <= new IP address
      inet6 fe80::966d:aeff:fe54:7222  prefixlen 64  scopeid 0x20<link>
      ether 94:6d:ae:54:72:22  txqueuelen 1000  (Ethernet)
      RX packets 2079478284  bytes 17618315075628 (17.6 TB)
      RX errors 0  dropped 8  overruns 0  frame 0
      TX packets 2082335328  bytes 17741532561365 (17.7 TB)
      TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

Changing or Adding Routes to the NIC

Change or add the routes under the proper interface in the configuration file and save the changes.

Figure 106. Nvidia A100 netplan additional routes example

```
jvd@A100-02:~$ route | grep gpu0
10.200.0.0   0.0.0.0         255.255.255.0   U     0      0        0 gpu0_eth
10.200.0.0   10.200.0.254    255.255.0.0     UG    0      0        0 gpu0_eth <= current routes

jvd@A100-01:/etc/netplan$ vi 01-netcfg.yaml
---more---
    gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:
        - 10.200.0.8/24
      routes:
        - to: 10.200.0.0/16
          via: 10.200.0.254
          from: 10.200.0.8 <= current routes
      set-name: gpu0_eth

jvd@A100-01:/etc/netplan$ vi 01-netcfg.yaml
---more---
    gpu0_eth:
      match:
        macaddress: 94:6d:ae:54:72:22
      dhcp4: false
      mtu: 9000
      addresses:
        - 10.200.0.18/24
      routes:
        - to: 10.200.0.0/16
          via: 10.200.0.254
          from: 10.200.0.8
        - to: 10.100.0.0/16
          via: 10.200.0.254    <= new route
      set-name: gpu0_eth
```

Apply the changes using the netplan apply command

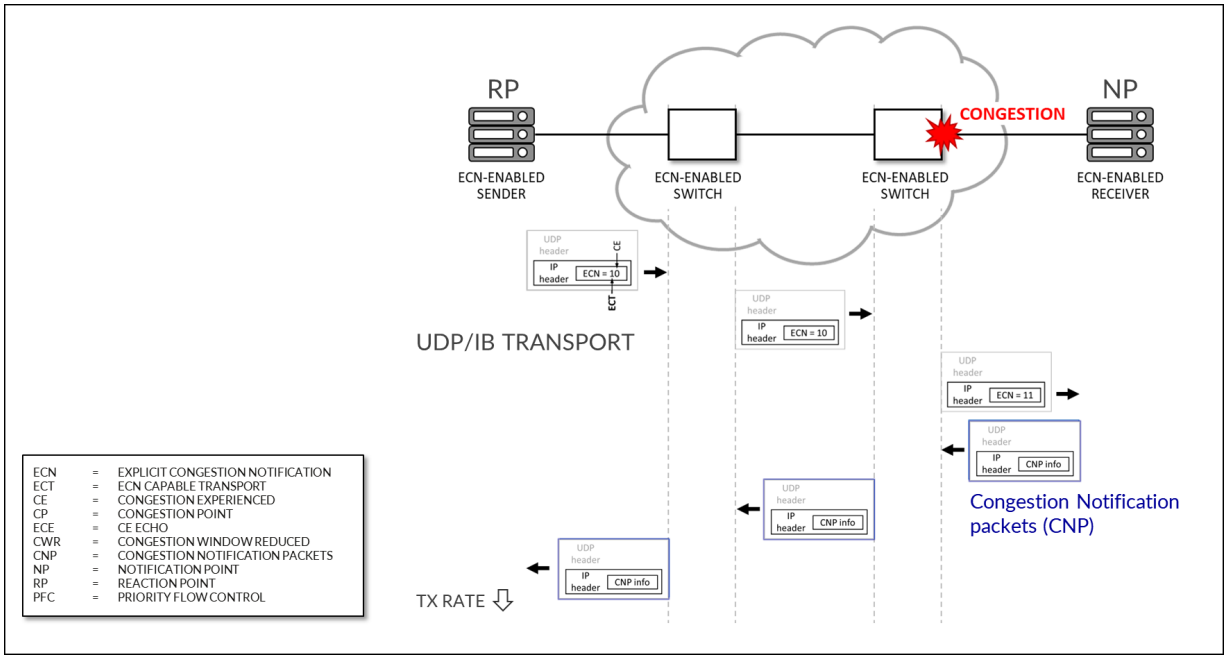
Figure 107. Nvidia A100 netplan additional routes application and verification example:

```
user@A100-01:/etc/netplan$ sudo netplan apply

user@A100-01:/etc/netplan$ route| grep gpu0
10.100.0.0      10.200.0.254    255.255.0.0     UG    0      0        0 gpu0_eth <= new route
10.200.0.0      0.0.0.0         255.255.255.0   U     0      0        0 gpu0_eth
10.200.0.0      10.200.0.254    255.255.0.0     UG    0      0        0 gpu0_eth
```

Configuring NVIDIA DCQCN – ECN

Figure 108: NVIDIA DCQCN – ECN



Starting from MLNX_OFED 4.1 ECN is enabled by default (in the firmware).

To confirm that ECN is enabled, use the following command: **mlxconfig -d <device> q | grep ROCE_CC**

Example:

- ```
  root@A100-01:/home/ylara# mlxconfig -d mlx5_0 q | grep ROCE_CC

          ROCE_CC_PRIO_MASK_P1          255

          ROCE_CC_PRIO_MASK_P2          255
  ```
  ```

A mask of 255 means DCQCN (ECN) is enabled for all TC (traffic classes) configured on the NIC.

To disable ECN, you can change the mask using the following command: **mlxconfig -d <device> s** ROCE_CC_PRIO_MASK_P1=<mask>

Example:

- ```
  root@A100-01:/home/ylara# sudo mlxconfig -d mlx5_0 s ROCE_CC_PRIO_MASK_P1=0

  Device #1:

  ----------

  Device type:    ConnectX7

  Name:           MCX755106AS-HEA_Ax

  Description:    NVIDIA ConnectX-7 HHHL Adapter Card; 200GbE (default mode) / NDR200 IB; Dual-port QSFP112; PCIe 5.0 x16 with x16 PCIe extension option; Crypto Disabled; Secure Boot Enabled

  Device:         mlx5_0

  Configurations:                                     Next Boot       New

           ROCE_CC_PRIO_MASK_P1                       0               0

   Apply new Configuration? (y/n) [n] :
  ```

If you want to avoid being asked whether you want to apply the new configuration you an include the -y option as shown in the following example:

- ```
  root@A100-01:/home/ylara# sudo mlxconfig -d mlx5_0 -y s ROCE_CC_PRIO_MASK_P1=0

  Device #1:

  ----------

  Device type:    ConnectX7

  Name:           MCX755106AS-HEA_Ax

  Description:    NVIDIA ConnectX-7 HHHL Adapter Card; 200GbE (default mode) / NDR200 IB; Dual-
  ```

```
port QSFP112; PCIe 5.0 x16 with x16 PCIe extension option; Crypto Disabled; Secure Boot
Enabled

Device:         mlx5_0

Configurations:                                     Next Boot       New

         ROCE_CC_PRIO_MASK_P1                       0               0

 Apply new Configuration? (y/n) [n] : y

Applying... Done!

-I- Please reboot machine to load new configurations.
```

The output states that a server reboot is required. As an alternative, you can reset the interface using the command: **mlxfwreset -d <device> -l 3 -y r.**

The device can be entered as /dev/mst/mt4129_pciconf2 or **mlx5_0** (gpu0_eth is not a valid format for this command)

Example:

- ```
  root@A100-01:/home/ylara# mlxfwreset -d mlx5_0 -l 3 -y r

  Requested reset level for device, /dev/mst/mt4129_pciconf2:

  3: Driver restart and PCI reset

  Continue with reset?[y/N] y

  -I- Sending Reset Command To Fw             -Done

  -I- Stopping Driver                         -Done

  -I- Resetting PCI                           -Done

  -I- Starting Driver                         -Done

  -I- Restarting MST                          -Done

  -I- FW was loaded successfully.
  ```
  ```

ECN operations parameters are located on the following path /sys/class/net/<interface>/ecn

Use the following command to find the interface:

- ```
  jvd@A100-01:~/$ ls /sys/class/net/

  docker0   enp14s0f1np1 enp17s0f1np1 enp44s0f1np1  gpu0_eth  gpu3_eth  gpu6_eth mgmt_eth

  enp139s0f1np1 enp169s0f0np0 enp200s0f1np1 enp81s0f1np1 gpu1_eth gpu4_eth gpu7_eth usb0

  enp142s0f1np1 enp169s0f1np1 enp203s0f1np1 enp82s0f1np1 gpu2_eth gpu5_eth lo

  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ ls

  roce_np  roce_rp
  ```

ECN bits on the IP header are always marked with 10 for RoCE traffic.

Notification Point (NP) Parameters

When the ECN-enabled receiver receives ECN-marked RoCE packets, it responds by sending CNP (Congestion Notification Packets).

The following commands describe the notification parameters:

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ ls /roce_np/

  cnp_802p_prio  cnp_dscp  enable  min_time_between_cnps
  ```

Examples:

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_np/cnp_802p_prio

  6
  ```

cnp_802p_prio = the value of the PCP (Priority Code Point) field of the CNP packets.

PCP is a 3-bit field within an Ethernet frame header when using VLAN tagged frames as defined by IEEE 802.1Q.
  ```

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_np/cnp_dscp

  48
  ```

cnp_dscp = the value of the DSCP (Differentiated Services Code Point) field of the CNP packets.

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_np/min_time_between_cnps

  4
  ```

min_time_between_cnps = minimal time between two consecutive CNPs sent. If the ECN-marked RoCE packet arrives in a period smaller than min_time_between_cnps since the previous sent CNP, no CNP will be sent as a response. This value is in microseconds. Default = 0

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_np/enable/*

  1

  1

  1

  1

  1

  1

  1

  1
  ```

The output shows that roce_np is enabled for all priority values.

NOTE: Sending CNP packets is handled globally per port, any priority enabled here will set sending CNP packets to on (1).

To change the attributes described above, use the **mlxconfig** utility:

- ```
  mlxconfig -d /dev/mst/<mst_module> -y s CNP_DSCP_P1=<value> CNP_802P_PRIO_P1=<value>
  ```

Example:

- ```
  jvd@A100-01:/dev/mst$ sudo mst start

  Starting MST (Mellanox Software Tools) driver set

  Loading MST PCI module - Success

  [warn] mst_pciconf is already loaded, skipping

  Create devices

  Unloading MST PCI module (unused) - Success

  jvd@A100-01:~/scripts$ ./map_full_mellanox.sh

```

Reaction Point (RP) Parameters

When the ECN-enabled sender receives CNP packets, it responds by slowing down transmission for the specified flows (priority).

The following parameters define how traffic flows will be rate limited, after CNP packets arrival:

- ```
  jvd@A100-01:/sys/class/net$ ls gpu0_eth/ecn/roce_rp/

  clamp_tgt_rate  enable  rpg_ai_rate     rpg_max_rate    rpg_time_reset

  clamp_tgt_rate_after_time_inc   initial_alpha_value     rpg_byte_reset  rpg_min_dec_fac
  ```
  ```

```
dce_tcp_g               rate_reduce_monitor_period              rpg_gd

rpg_min_rate            dce_tcp_rtt     rate_to_set_on_first_cnp

rpg_hai_rate                    rpg_threshold
```

Examples:

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_rp/enable/*

  1

  1

  1

  1

  1

  1

  1

  1

  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ cat roce_rp/rpg_max_rate

  0
  ```

rpg_max_rate = Maximum rate at which reaction point node can transmit. Once this limit is reached, RP is no longer rate limited.

This value is configured in Mbits/sec. Default = 0 (full speed – no max)

The output shows that roce_rp is enabled for all priority values.

NOTE: Handling CNP is configured per priority.

To check the ECN statistics use: ethtool -S <interface> | grep ecn

Example:
  ```

- ```
  jvd@A100-01:~/scripts$ ethtool -S gpu0_eth | grep ecn
       rx_ecn_mark: 0
       rx_xsk_ecn_mark: 0
       rx0_ecn_mark: 0
       rx1_ecn_mark: 0
       rx2_ecn_mark: 0
       rx3_ecn_mark: 0
       rx4_ecn_mark: 0
       rx5_ecn_mark: 0
       rx6_ecn_mark: 0

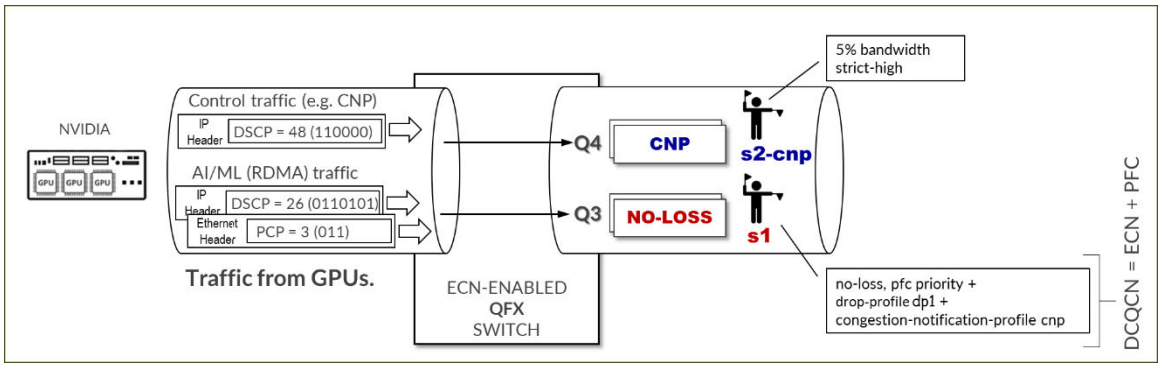
     tx_pause_storm_error_events: 0
```

NOTE: The Pause counters are visible via ethtool only for priorities on which PFC is enabled.

NVIDIA TOS/DSCP Configuration for RDMA-CM QPS (RDMA Traffic)

Figure 110: NVIDIA TOS/DSCP



RDMA traffic must be properly marked to allow the switch to correctly classify it, and to place it in the lossless queue for proper treatment. Marking can be either DSCP within the IP header, or PCP in the ethernet frame vlan-tag field. Whether DSCP or PCP is used depends on whether the interface between the GPU server and the switch is doing vlan tagging (802.1q) or not.

To check the current configuration and to change the values of TOS for the RDMA outbound traffic, use the **cma_roce_tos** script that is part of MLNX_OFED 4.0.

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ sudo cma_roce_tos -h

  Set/Show RoCE default TOS of RDMA_CM applications

  Usage:

          cma_roce_tos OPTIONS

  Options:

          -h              show this help

          -d <dev>        use IB device <dev> (default mlx5_0)

          -p <port>       use port <port> of IB device (default 1)

          -t <TOS>        set TOS of RoCE RDMA_CM applications (0)
  ```

To check the current value of the TOS field, enter sudo cma_roce_tos without any options.

Example:
  ```

- ```
  jvd@A100-01:/sys/class/net/gpu0_eth/ecn$ sudo cma_roce_tos

  106
  ```

In the example, the current TOS value = 106, which means a DSCP value = 48, and the ECN bits set to 10.

NOTE: The TOS field is 8 bits, while the DSCP is 6 bits. To set a DSCP value of X, you need to multiply this value by 4 (SHIFT 2). For example, to set DSCP value of 24, (24x4=96). Set the TOS bit to 96. You need to add 2 to include the ECN.

	TYPE OF SERVICE FIELD (TOS) BINARY								TOS		DSCP		IP PRECEDENCE		
									DECIMAL VALUE	HEX VALUE	DECIMAL VALUE	HEX VALUE	DECIMAL VALUE	HEX VALUE	NAME
CNP	1	1	0	0	0	0	1	0	194	0xC2	48	0x30	6	0x6	Internetwork Control
NO-LOSS	0	1	1	0	1	0	1	0	106	0x6A	26	0x1A	3	0x3	Flash

To change the value use: cma_roce_tos –d <ib_device> -t <TOS>

You need to enter the ib_device in this command. The following script automatically does the mapping between the physical interfaces and the ib_device.

- ```
  map_full_mellanox.sh

  #!/bin/bash

  # Script to map Mellanox devices to mlx and network interfaces

  # Get Mellanox device PCI addresses

  mst_status=$(sudo mst status | awk '

  /\/dev\/mst/ {

      dev = $1

  }
  ```

```
/domain:bus:dev.fn/ {

    pci = $1

    printf "%s: %s\n", dev, pci

}

')

# Get network interface PCI addresses

iface_status=$(for iface in $(ls /sys/class/net/); do

    pci_addr=$(ethtool -i $iface 2>/dev/null | grep bus-info | awk '{print $2}')

    if [ ! -z "$pci_addr" ]; then

        echo "$iface: $pci_addr"

    fi

done)

# Get network interface to mlx interface mapping

mlx_iface_status=$(for iface in $(ls /sys/class/net/); do

    if [ -d /sys/class/net/$iface/device/infiniband_verbs ]; then

        mlx_iface=$(cat /sys/class/net/$iface/device/infiniband_verbs/*/ibdev)

        echo "$iface: $mlx_iface"

    fi

done)

# Combine and print the mapping

echo "Mellanox Device to mlx and Network Interface Mapping:"
```

```
echo "$mst_status" | while read -r mst_line; do

    mst_dev=$(echo $mst_line | awk -F ': ' '{print $1}')

    mst_pci=$(echo $mst_line | awk -F '=| ' '{print $3}')

    iface=$(echo "$iface_status" | grep $mst_pci | awk -F ': ' '{print $1}')

    iface_pci=$(echo "$iface_status" | grep $mst_pci | awk -F ': ' '{print $2}')

    mlx_iface=$(echo "$mlx_iface_status" | grep $iface | awk -F ': ' '{print $2}')

    if [ ! -z "$iface" ] && [ ! -z "$mlx_iface" ]; then

        echo "$mst_dev => $mlx_iface => $iface ($iface_pci)"

    fi

done
```

Example:

Figure 111. script results example

```
jvd@A100-01:~/scripts$ ./map_full_mellanox.sh

Configuring NVIDIA to Use the Management Interface for NCCL Control Traffic

NCCL uses TCP sessions to connect processes together and exchange QP information for RoCE, GIDs (Global IDs), Local and remote buffer addresses, RDMA keys (RKEYs for memory access permissions)

These are separate to the RoCEv2 traffic (port 4791) used for synchronizing model parameters, partial results of operations, and so on.

These sessions are created when the job starts and by default use one of the GPU interfaces (same interfaces used for RoCEv2 traffic).

Example:

- ```
  ylara@A100-01:~$ netstat -atn | grep 10.200 | grep "ESTABLISHED"

  tcp        0      0 10.200.4.8:47932        10.200.4.2:43131        ESTABLISHED

  tcp        0      0 10.200.4.8:46699        10.200.4.2:37236        ESTABLISHED
  ```
  ```

```
tcp        0      0 10.200.2.8:60502        10.200.13.2:35547       ESTABLISHED

tcp        0      0 10.200.4.8:37330        10.200.4.2:55355        ESTABLISHED

tcp        0      0 10.200.4.8:56438        10.200.4.2:53947        ESTABLISHED

---more---
```

It is recommended, move to the management interface (connected to the (Frontend Fabric) including the following parameter when starting a job: **export NCCL_SOCKET_IFNAME="mgmt_eth"**

Example:

- ```
  ylara@A100-01:~$ netstat -atn | grep 10.10.1 | grep "ESTABLISHED"

  tcp        0      0 10.10.1.0:44926         10.10.1.2:33149         ESTABLISHED

  tcp        0      0 10.10.1.0:46705         10.10.1.0:40320         ESTABLISHED

  tcp        0      0 10.10.1.0:54661         10.10.1.10:52452        ESTABLISHED

  ---more---
  ```

ECN is enabled by default for these sessions; ***net.ipv4.tcp_ecn = 1*** , but can be disable with: ***sudo sysctl -w net.ipv4.tcp_ecn=0***

WEKA Storage Solution

IN THIS SECTION
  ```

The WEKA Data Platform is a software-based solution built to modernize enterprise data stacks. Its advanced AI-native, data pipeline-oriented architecture delivers high performance at scale, so AI workloads run faster and work more efficiently.

We selected the WEKA Data Platform as part of the AI JVD design due to the following benefits:

- **High Performance**: Weka's architecture is designed for extreme performance, making it suitable for AI/ML workloads, big data analytics, and high-performance computing (HPC) environments.
- **Scalability**: Weka can scale from a few terabytes to exabytes of data, allowing customers to grow their storage capacity without compromising performance. WEKA's distributed architecture differs from typical scale-up style storage systems, appliances, and hypervisor-based, software-defined storage solutions. It overcomes traditional storage scaling and file-sharing limitations that can be a bottleneck to large-scale AI deployments, making one of the preferred choices for customers.
- **Unified Storage**: Weka provides a single storage solution that can support multiple protocols (e.g., NFS, SMB, POSIX, S3), providing flexibility to access and manage the data and allowing Nvidia's GPUDirect Storage access.
- **Data Resilience**: Weka offers advanced data protection features, including erasure coding, which ensures data resilience and protection against hardware failures. With a minimum configuration of six storage servers, the cluster can survive two-server failure.
- **Ease of Management**: Weka's software-defined storage solution is easy to deploy and manage, with a user-friendly interface and automated management features. It can be installed on any standard AMD EPYC™ or Intel Xeon™ Scalable Processor-based hardware with the appropriate memory, CPU processor, networking, and NVMe solid-state drives.
- **Support for GPUs**: Weka is optimized for GPU acceleration, making it an ideal storage solution for environments that heavily rely on GPU computing, such as AI and machine learning applications.
- **Low Latency**: The architecture of Weka allows for very low-latency access to data, which is crucial for applications that require real-time data processing.

Weka storage cluster in the AI JVD lab

We built the WEKA storage cluster with eight SuperMicro-based servers connected to the Storage Backend fabric providing **242TB** of usable storage. WEKA recommends eight cluster nodes and requires a minimum of six nodes for production deployment.

Each WEKA Server has the following specifications

- AMD EPYC 9454P processors
- 384GB System Memory

- OS drives: 2x 1.92TB M.2 NVMe Data Center SSD (PCIe 4.0)
- Data drives: 7x 7.68TB U.2 NVMe Data Center SSD (PCIe 4.0)
- Onboard OOB network connection (RJ45) and the following additional interface cards:
  - 1 x NVIDIA Mellanox ConnectX-6 DX Adapter Card, 100GE, dual-port QSFP28, PCIe 4.0 x16
  - 2 x NVIDIA Mellanox ConnectX-6 VPI Adapter Card, HDR IB & 200GE, dual-port QSFP56, OCP 3.0
- Software:
  - The operating system installed is Ubuntu 22.04 LTS.
  - WEKA release version tested in this design is 4.2.5.
  - WEKA Flash Tier license w/SnapShot and high-performance protocol services
  - (POSIX, NFS-W, S3 and SMB-W)

Common Setting Changes Required

WEKA strongly recommends certain BIOS settings, and that Mellanox drivers are matched across all nodes. For convenience, these changes are documented here.

NOTE: WEKA makes available a Weka Management Service (WMS) tool that can be used to automate the BIOS settings changes, verify your configuration, including driver revisions, and deploy the WEKA version you have. This can be downloaded from the WEKA website, located here: https://get.weka.io/ui/wms/download. Juniper highly recommends utilizing the WMS for configuring the WEKA cluster. All the devices are configured to perform ECMP load balancing, as explained later in the document.

BIOS settings:

The BIOS settings can be changed by applying the bios_settings.yml:

- ```
  Supermicro:

    AMD:

      ACPISRATL3CacheAsNUMADomain#0099: Disabled

      IOMMU#00EA: Disabled
  ```
  ```

```
NUMANodesPerSocket#703F: Auto

SMTControl#00CB: Disabled

SR-IOVSupport#0067: Enabled

DFCstates#7104: Disabled

GlobalC-stateControl#00CD: Disabled
```

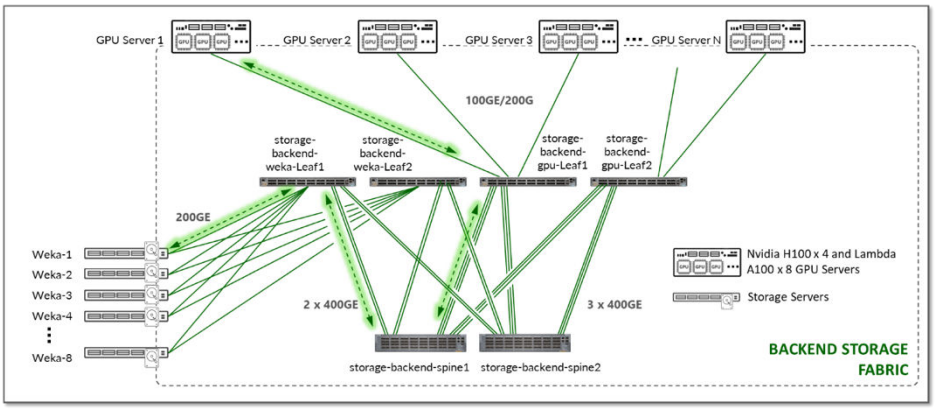
This is an AMD CPU-powered cluster; the settings may be different for Intel based CPUs.

For more details on how to apply these changes refer to: GitHub - weka/bios_tool: A tool for viewing/setting bios_settings for Weka servers

Network Configuration for the Juniper WEKA Cluster

As described in the Storage Backend sections, the WEKA servers are dual-homed, and are connected to separate storage backend switches (***storage-backend-weka-leaf*** 1 and ***storage-backend-weka-leaf*** 2) using 200GE ports in the NVIDIA Mellanox ConnectX-6 VPI Adapter Card. The additional QSFP28 100Gbe ports are not used in this JVD but can be used for front-end ingress/egress traffic, staging and management.

Figure 113: Storage Interface Connectivity



The ports on the switch side must be configured with no auto negotiation and set to 200G speed.

OFED Drivers:

WEKA recommends following Nvidia's recommendation for OFED (Mellanox) drivers when using Connect-X cards. NVIDIA Documentation - Installing Mellanox OFED.

Driver Release Should be 5.8 or Later

Ensure that all versions for OFED drivers are aligned across all nodes in the WEKA cluster (i.e. ensure weka01 has the appropriate OFED installed).

For Ubuntu, the following command is recommended:

- ```
  ./mlnxofedinstall --force --dkms --all.
  ```

The following script can also be run (as root) on all machines to set the appropriate Mellanox firmware settings.

- ```
  #!/bin/bash

  mst start

  for MLXDEV in /dev/mst/* ; do

      mlxconfig -d ${MLXDEV} -y s ADVANCED_PCI_SETTINGS=1 PCI_WR_ORDERING=1

      mlxfwreset -y -d ${MLXDEV} reset

  done

  netplan apply

  mst stop
  ```

Best Practices for WEKA Data Platform with Juniper Switches

Our cluster is configured using the WEKA distributed POSIX client, which requires some tuning to be integrated to the rest of the design.

We recommend the following:

- Set the MTU to 9000
- If the back-end storage fabric is shared with another resource, set up appropriate CoS prioritization to ensure the AI ingest and checkpoint traffic is not interrupted by other applications' network I/O requests.
- If GPU Direct Storage is being used instead of the WEKA distributed POSIX client, congestion management and mitigation capability on the network utilizing Explicit Congestion Notification (ECN) and Priority Flow Control (PFC) must be set up.

WEKA also provides tools that can be used to test and measure network activity from a WEKA system perspective.

The command line tool ‘weka stats’ reports a percentage output of ‘good’ network performance.

- ```
  weka stats --start-time -24h --end-time -1m --show-

  internal  --stat GOODPUT_TX_

  RATIO,GOODPUT_RX_RATIO
  ```

When the output is shown as a percentage, anything below 85% indicates potential issues that require further examination.

Examples:

- ```
  NODE  CATEGORY  TIMESTAMP          STAT                      VALUE

  all   network   2024-06-14T12:58:00  GOODPUT_RX_RATIO  99.7636 %

  all   network   2024-06-14T12:58:00  GOODPUT_TX_RATIO  99.7636 %

  all   network   2024-06-14T12:57:00  GOODPUT_RX_RATIO  99.7663 %

  all   network   2024-06-14T12:57:00  GOODPUT_TX_RATIO  99.7663 %

  all   network   2024-06-14T12:56:00  GOODPUT_RX_RATIO  99.752 %

  all   network   2024-06-14T12:56:00  GOODPUT_TX_RATIO  99.752 %

  all   network   2024-06-14T12:55:00  GOODPUT_RX_RATIO  99.7578 %
  ```

```
all   network   2024-06-14T12:55:00  GOODPUT_TX_RATIO  99.7578 %

all   network   2024-06-14T12:54:00  GOODPUT_RX_RATIO  99.7795 %

all   network   2024-06-14T12:54:00  GOODPUT_TX_RATIO  99.7795 %

all   network   2024-06-14T12:53:00  GOODPUT_RX_RATIO  99.7685 %

all   network   2024-06-14T12:53:00  GOODPUT_TX_RATIO  99.7685 %

all   network   2024-06-14T12:52:00  GOODPUT_RX_RATIO  99.775 %

all   network   2024-06-14T12:52:00  GOODPUT_TX_RATIO  99.775 %
```

weka stats --category=network --show-internal --stat DROPPED_PACKETS --start-time -24h --end-time -1m -Z

- ```
  NODE  CATEGORY  TIMESTAMP               STAT               VALUE

  all   network   2024-06-14T13:06:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:05:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:04:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:03:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:02:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:01:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T13:00:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T12:59:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T12:58:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T12:57:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T12:56:00  DROPPED_PACKETS  0 Packets/Sec

  all   network   2024-06-14T12:55:00  DROPPED_PACKETS  0 Packets/Sec
  ```
  ```

```
all   network   2024-06-14T12:54:00  DROPPED_PACKETS  0 Packets/Sec

all   network   2024-06-14T12:53:00  DROPPED_PACKETS  0 Packets/Sec
```

If the weka stats command reports dropped packets as shown, further investigation is warranted.

More details and additional tools can be found on the WEKA website Manually prepare the system for WEKA configuration | W E K A.

Network Connectivity Details (Reference Examples)

IN THIS SECTION

For those who want more details, this section provides insight into the setup of each fabric and the expected values for the reference examples.

The section describes the IP connectivity across the common Frontend, and Storage Backend fabrics, and the GPU Backend fabric in Cluster 1, Stripe 1. The GPU Backend fabrics for cluster 1, stripe 2, and cluster 2 follow the same model.

Regardless of whether you are using Apstra with or without Terraform automation **with** Apstra, the IP addressing Pools, ASN Pools, and interface addresses are largely automatically assigned and configured with little interaction from the administrator unless desired.

Notice that all the addresses shown in this section represent the IP addressing schema used in the Juniper lab to validate the design.

Frontend Network Connectivity

The Frontend fabric is designed as a Layer 3 IP Fabric, where the links between the leaf and spine nodes are configured with /31 IP addresses, as shown in Table 31. The fabric consists of 2 spine nodes and 2 leaf nodes, where 1 leaf node is used to connect to the storage servers (named ***frontend-weka-leaf** 1)* and 1 is used to connect to the GPU servers (named *frontend-ai-leaf1).* Additionally, the Headend Servers that execute the workload manager (Slurm) for AI Training and Inference models reside in this fabric.

In this example, leaf nodes connecting to the GPU servers in the Frontend fabric are named ***frontend-ai-leaf#*** *instead of* ***frontend-gpu-leaf#*** *, but they represent the same role.*

There are two 400GE links between each ***frontend-weka-leaf** 1* node and the spine nodes, and two 400GE links between each *frontend-ai-leaf1* node and the spine nodes as shown in Figure 114.

Figure 114: Frontend Spine to Leaf Nodes Connectivity

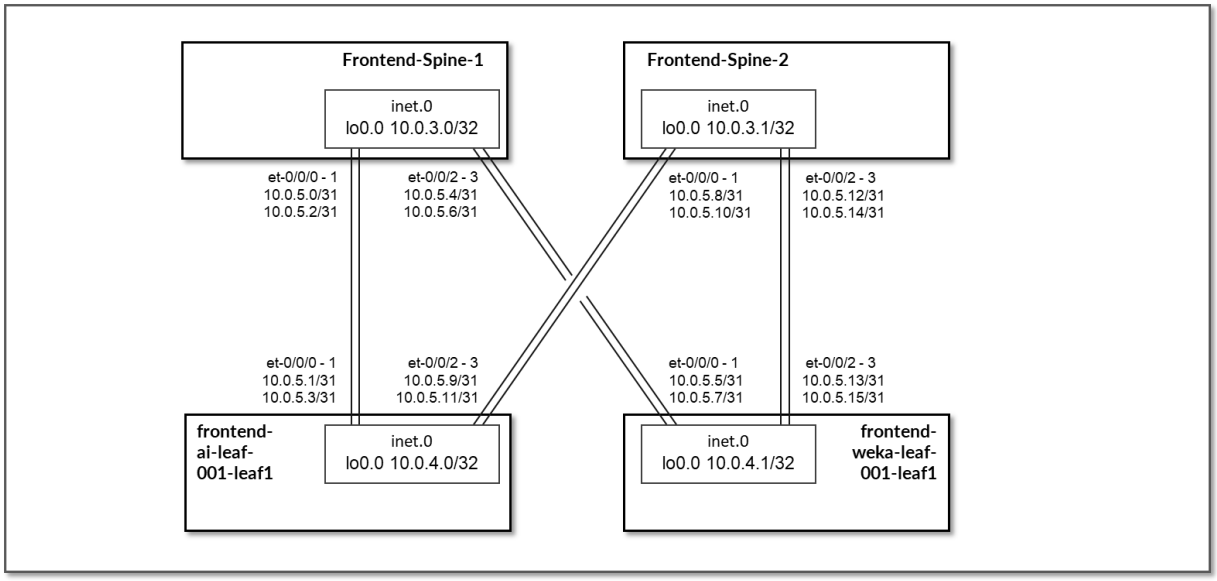


Table 31: Frontend Interface Addresses

Spine node	Leaf node	Spine IP address	Leaf IP address
frontend-spine1	*frontend-ai-leaf1*	10.0.5.0/31 10.0.5.2/31	10.0.5.1/31 10.0.5.3/31
frontend-spine1	*frontend-weka-leaf1*	10.0.5.4/31 10.0.5.6/31	10.0.5.5/31 10.0.5.7/31

(Continued)

Spine node	Leaf node	Spine IP address	Leaf IP address
frontend-spine2	*frontend-ai-leaf1*	10.0.5.8/31 10.0.5.10/31	10.0.5.9/31 10.0.5.11/31
frontend-spine2	*frontend-weka-leaf1*	10.0.5.12/31 10.0.5.14/31	10.0.5.13/31 10.0.5.15/31

NOTE: all the Autonomous System and IP addresses are assigned by Apstra (from predefined pools of resources) based on the intent.

The loopback interfaces also have addresses automatically assigned by Apstra from a predefined pool.

Table 32: Frontend Loopback Addresses

Device	Loopback interface address
frontend-spine1	10.0.3.0/32
frontend-spine2	10.0.3.1/32
frontend-ai-leaf1	10.0.1.0/32
frontend-weka-leaf1	10.0.1.1/32

The H100 GPU Servers and A100 GPU Servers are all connected to the frontend-ai-leaf1 node.

The links between the GPU servers and the leaf node Leaf 1 are assigned /31 subnets out of 10.0.5.0/24, shown in Figure 115 and Table 33.

Figure 115: Frontend Leaf Nodes to GPU Servers Connectivity

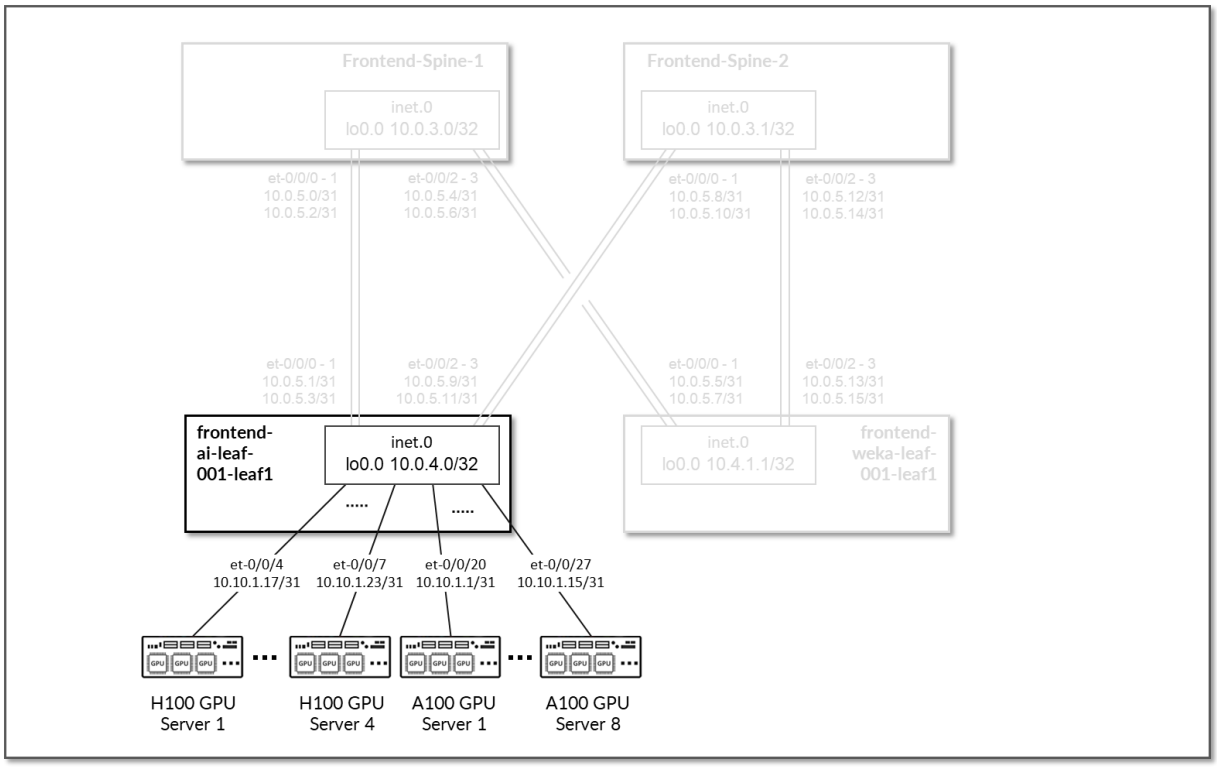

Table 33: Frontend Leaf Nodes to GPU Servers Interfaces Addresses

GPU Server	Leaf node	GPU Server IP address	Leaf IP address
H100 GPU Server 1	*frontend-ai-leaf1*	10.10.1.17/31	10.100.1.9/31
H100 GPU Server 2		10.10.1.19/31	10.100.1.11/31
H100 GPU Server 3		10.10.1.21/31	10.100.1.1/31
H100 GPU Server 4		10.10.1.23/31	10.100.1.3/31
A100 GPU Server 1		10.10.1.1/31	10.100.1.5/31
A100 GPU Server 2		10.10.1.3/31	10.100.1.7/31
A100 GPU Server 3		10.10.1.5/31	10.100.2.9/31
A100 GPU Server 4		10.10.1.7/31	10.100.2.11/31

(Continued)

GPU Server	Leaf node	GPU Server IP address	Leaf IP address
A100 GPU Server 5		10.10.1.9/31	10.100.2.1/31
A100 GPU Server 6		10.10.1.11/31	10.100.2.3/31
A100 GPU Server 7		10.10.1.13/31	10.100.2.5/31
A100 GPU Server 8		10.10.1.15/31	10.100.2.7/31

The WEKA storage servers are all connected to the ***frontend-weka-leaf*** 1 node.

The links to these servers do not have IP addresses assigned on the leaf node. Layer 3 connectivity is provided via an irb interface with an address out of subnet 10.10.2.1/24. The WEKA servers are assigned addresses out of 10.10.2.0/24, as shown in Figure 116 and Table 34.

Figure 116: Frontend Leaf Nodes to WEKA Storage Connectivity

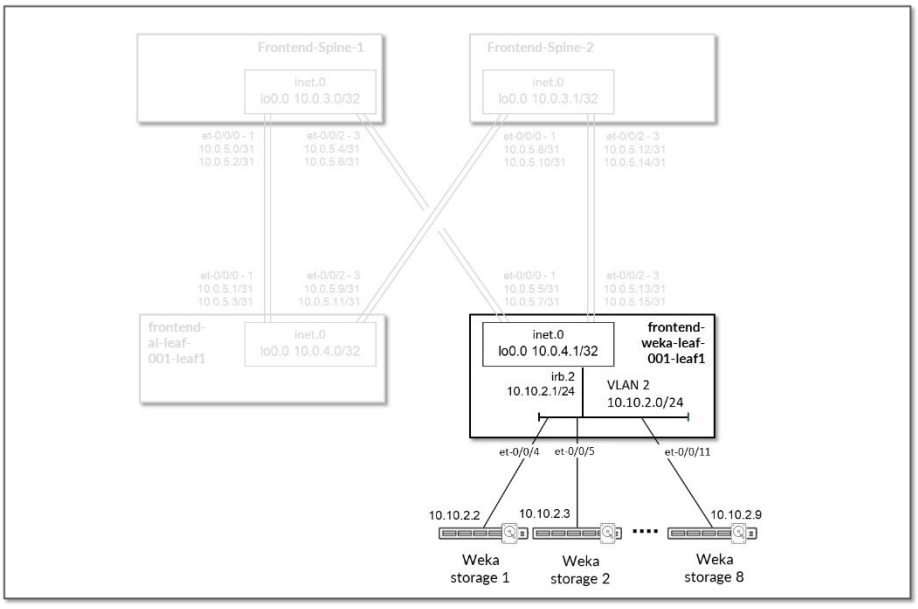

Table 34: Frontend Leaf Nodes to WEKA Storage Interface Addresses

GPU Server	Leaf node	WEKA Server IP Address	Leaf IP Address
WEKA Storage Server 1	***frontend-weka-leaf1***	10.10.2.2/24	10.10.2.1/24 (irb.2)
WEKA Storage Server 2		10.10.2.3/24	

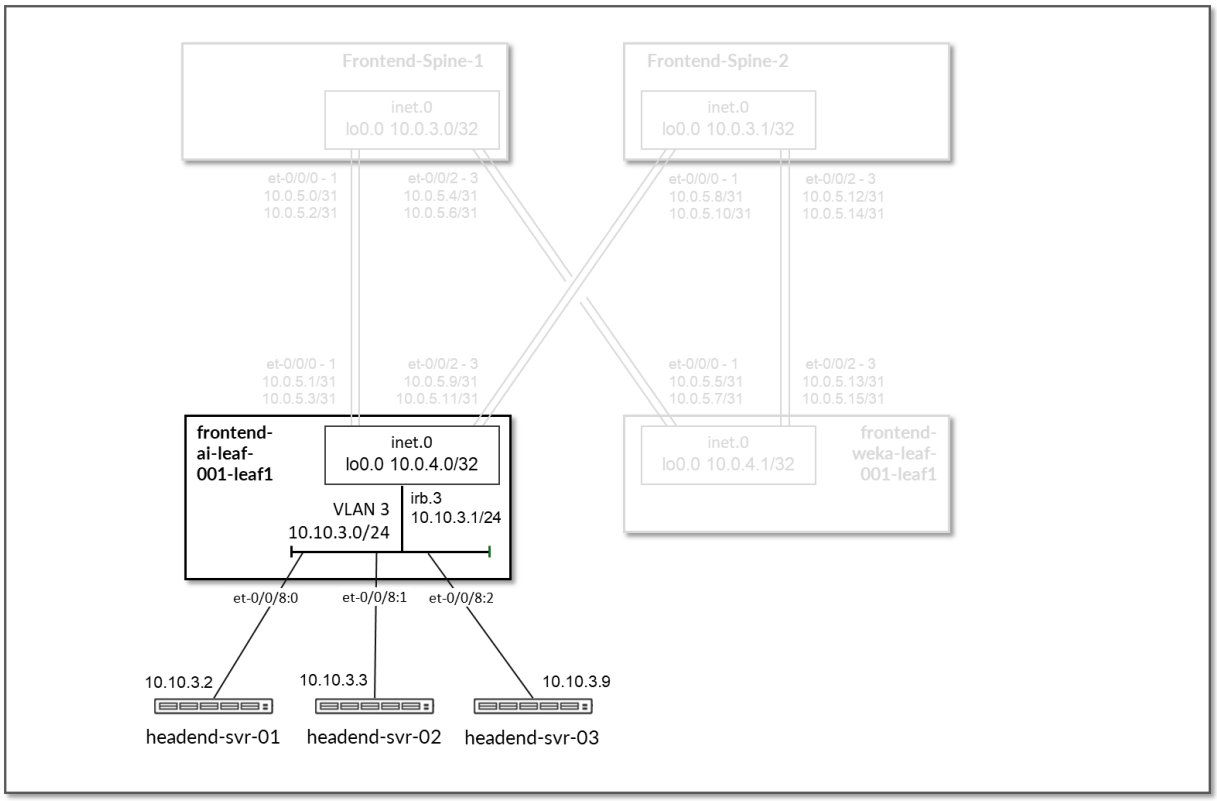
(Continued)

GPU Server	Leaf node	WEKA Server IP Address	Leaf IP Address
WEKA Storage Server 3		10.10.2.4/24	
WEKA Storage Server 4		10.10.2.5/24	
WEKA Storage Server 5		10.10.2.6/24	
WEKA Storage Server 6		10.10.2.7/24	
WEKA Storage Server 7		10.10.2.8/24	
WEKA Storage Server 8		10.10.2.9/24	

The Headend servers executing the workload manager are all connected to the frontend-ai-leaf1 node.

The links to these servers do not have IP addresses assigned on the leaf node. Layer 3 connectivity is provided via an irb interface with the address 10.10.3.1/24. The headend servers assigned addresses out of 10.10.3.0/24, as shown in Figure 117 and table below.

Figure 117: Frontend Leaf Nodes to Headend Servers Connectivity



EBGP is configured between the IP addresses assigned to the spine-leaf nodes links. There will be 2 EBGP sessions between the *frontend-ai-leaf#* node and each spine node, and 2 EBGP sessions between each ***frontend-weka-leaf #*** node and each of the spine nodes, as shown in Figure 118.

Figure 118: Frontend EBGP

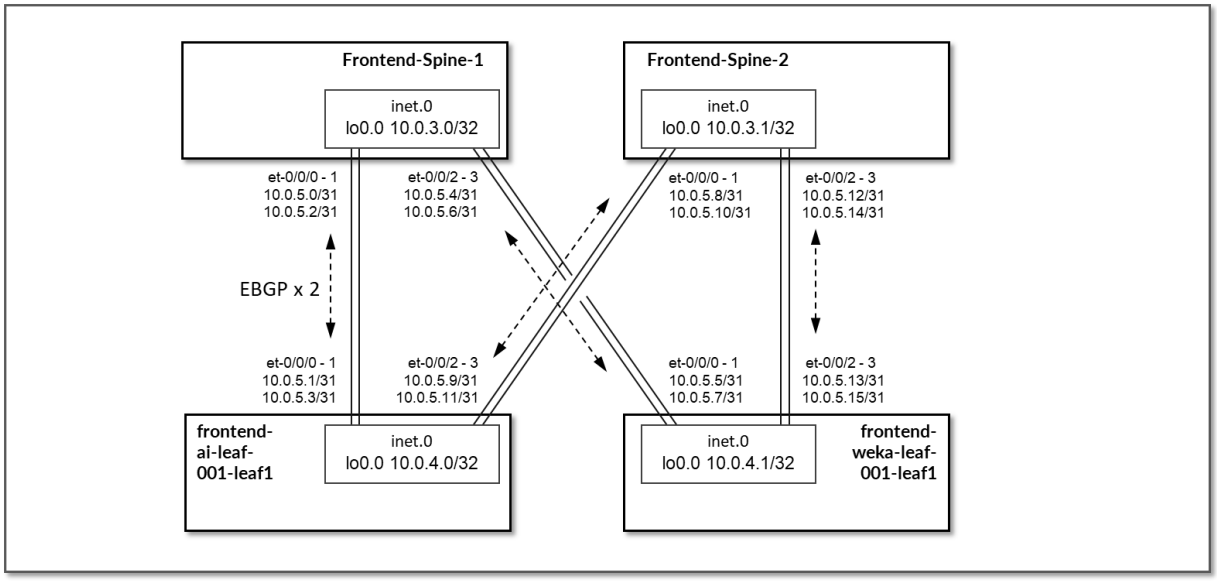


Table 35: Frontend Sessions

Spine node	Leaf node	Spine	Leaf ASN	Spine IP address	Leaf IP address
frontend-spine1	*frontend-ai-leaf1*	4201032300	4201032400	10.0.5.0/31 10.0.5.2/31	10.0.5.1/31 10.0.5.3/31
frontend-spine1	*frontend-weka-leaf* 1		4201032401	10.0.5.4/31 10.0.5.6/31	10.0.5.4/31 10.0.5.7/31
frontend-spine2	*frontend-ai-leaf1*	4201032301	4201032400	10.0.5.8/31 10.0.5.10/31	10.0.5.9/31 10.0.5.11/31
frontend-spine2	*frontend-weka-leaf* 1		4201032401	10.0.5.12/31 10.0.5.14/31	10.0.5.13/31 10.0.5.15/31

NOTE: all the Autonomous System and community values are assigned by Apstra (from predefined pools of resources) based on the intent.

On the frontend-ai-leaf1 nodes BGP policies are configured by Apstra to advertise the following routes to the spine nodes:

- frontend-ai-leaf1 node own loopback interface address,
- frontend-ai-leaf1 node to spines interfaces subnets and
- GPU servers to frontend-ai-leaf1 node link subnets.
- WEKA server's management subnet

Figure 119: Frontend Leaf to GPU Servers BGP

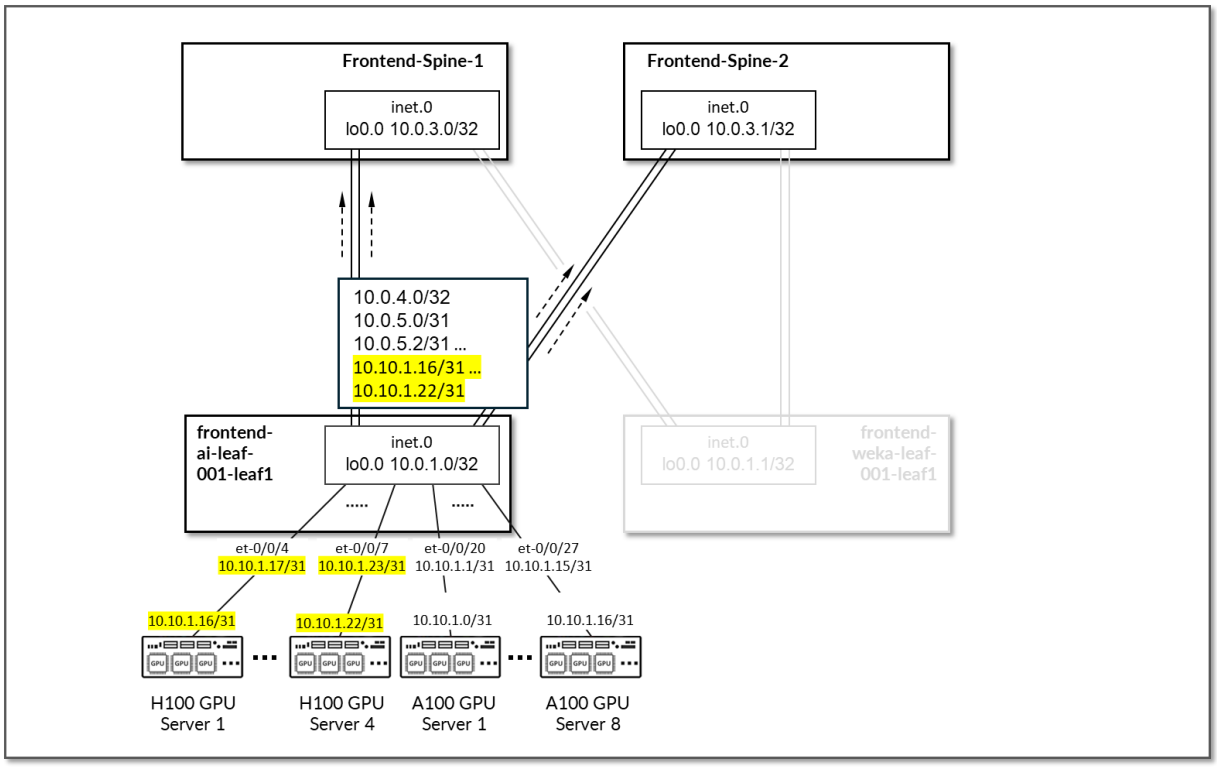

Figure 120: Frontend Leaf to Headend Server BGP

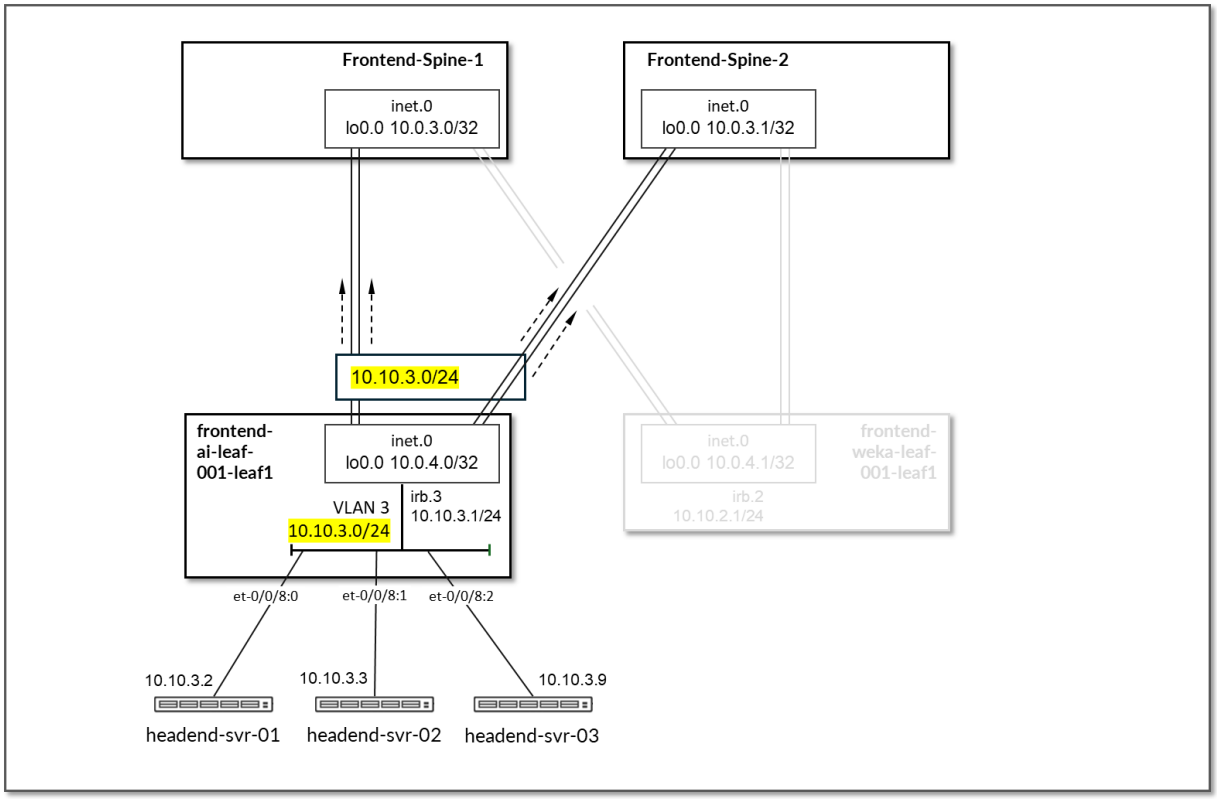

Table 36: Frontend Leaf to GPU/Headend Servers Advertised Routes

Leaf Node	Peer(s)	Advertised Routes		BGP Communities
frontend-ai-leaf1	*frontend-spine1 & frontend-spine2*	Loopback: 10.0.4.0/32 Leaf-spines links: 10.0.5.0/31 10.0.5.2/31 10.0.5.8/31 10.0.5.10/31	GPU servers <=> frontend spine links: 10.10.1.16/31 10.10.1.18/31 10.10.1.20/31 10.10.1.22/31 10.10.1.0/31 10.10.1.2/31 10.10.1.4/31 10.10.1.6/31 10.10.1.8/31 10.10.1.10/31 10.10.1.12/31 10.10.1.14/31 WEKA Management server's subnet: 10.10.3.0/24	3:20007 21001:26000

On the *frontend-weka-leaf* 1 node BGP policies are configured by Apstra to advertise the following routes to the spine nodes:

- *frontend-weka-leaf* 1 node own loopback interface address,
- *frontend-weka-leaf* 1 node to spines interfaces subnets and
- WEKA storage server's subnet

Figure 121: Frontend Leaf to WEKA Storage BGP

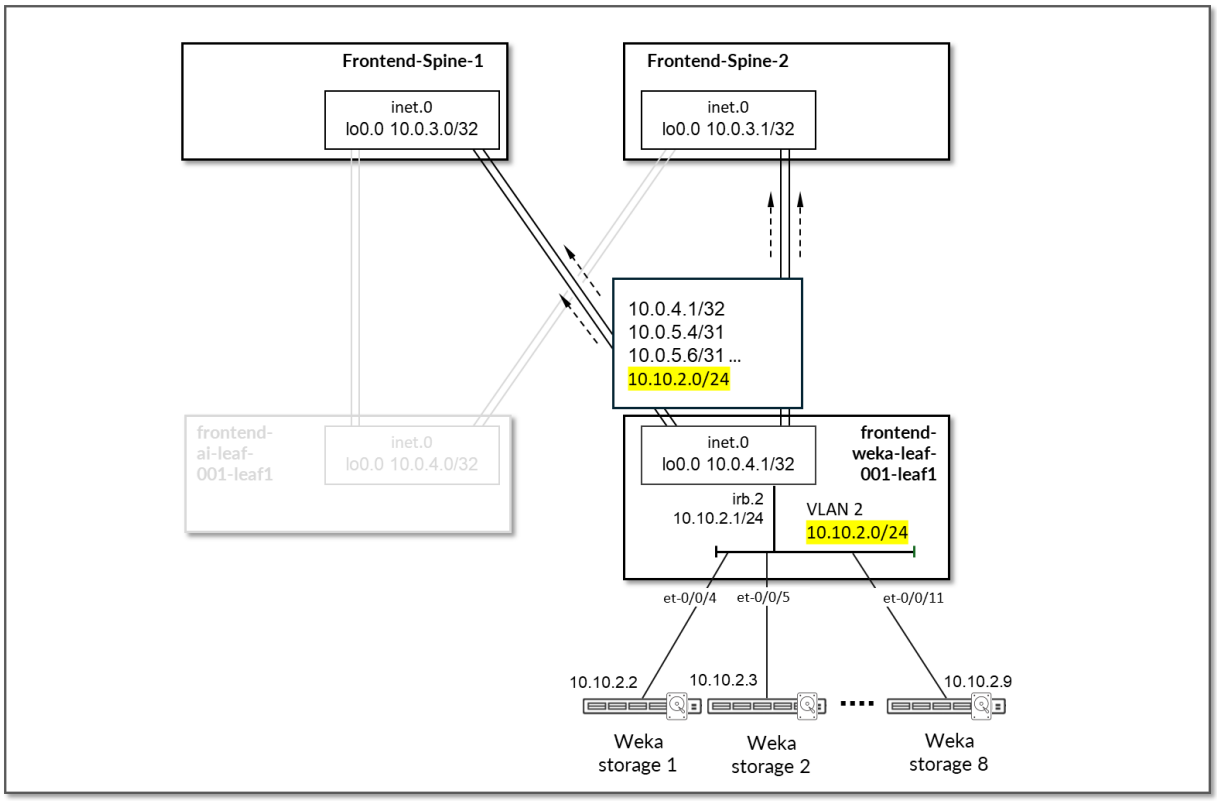

Table 37: Frontend Leaf to Weka Storage Advertised Routes

Leaf Node	Peer(s)	Advertised Routes		BGP Communities
frontend-weka-leaf 1	*frontend-spine1* & *frontend-spine2*	Loopback: 10.0.4.1/32 Leaf-spines links: 10.0.5.4/31 10.0.5.6/31 10.0.5.12/31 10.0.5.14/31	GPU servers <=> frontend spine links: 10.10.2.0/24	4:20007 21001:26000

On the Spine nodes, BGP policies are configured by Apstra to advertise the following routes to the frontend-ai-leaf node:

- *frontend-spine* node own loopback interface address
- *frontend-weka-leaf* 1 loopback interface address

- ***frontend-spine*** to ***frontend-weka-leaf*** 1 nodes interfaces subnets
- WEKA storage server's subnet (learned from ***frontend-weka-leaf*** 1)

Figure 122: Frontend Spine to Frontend Leaf for GPU/Headed Servers BGP

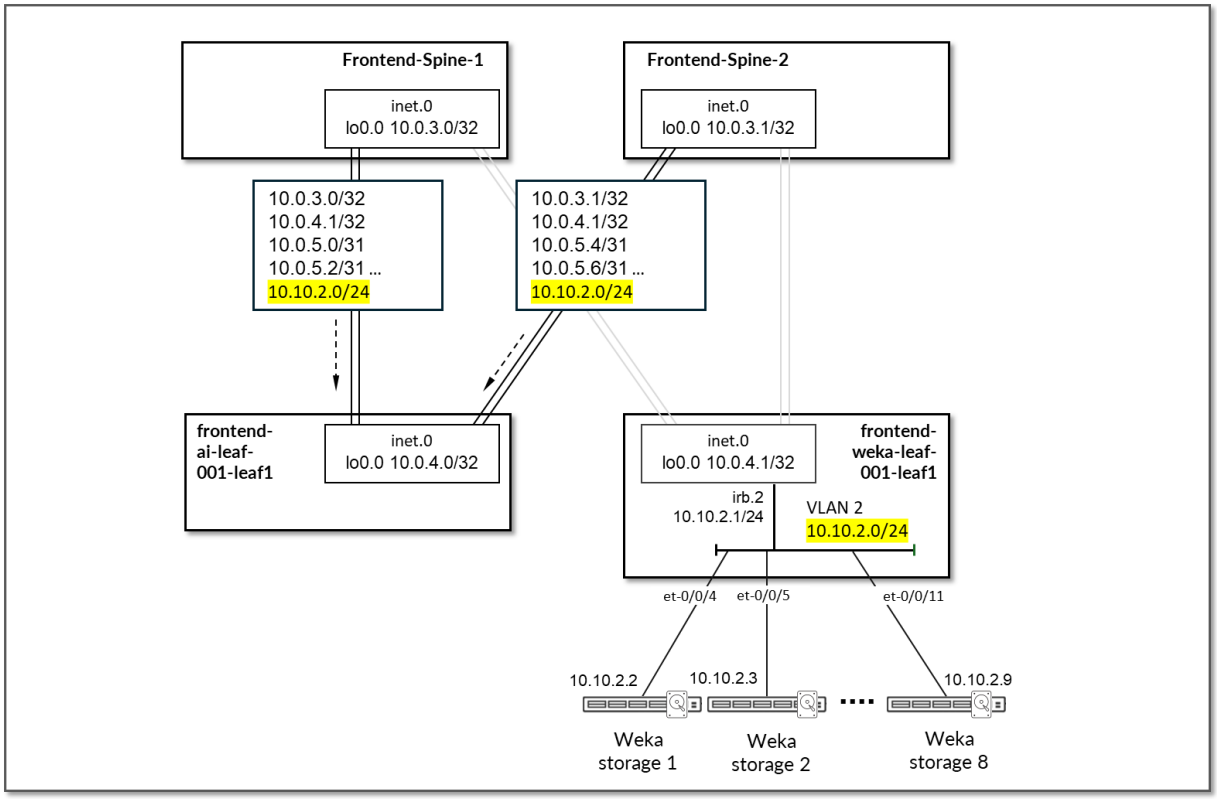

Table 38: Frontend Spine to Frontend Leaf for GPU/Headed Servers Advertised Routes

Leaf Node	Peer(s)	Advertised Routes		BGP Communities
frontend-spine1	*frontend-ai-leaf*	Loopback: 10.0.3.0/32 10.0.4.0/32 Leaf-spines links: 10.0.5.0/31 10.0.5.2/31 10.0.5.4/31 10.0.5.6/31 10.0.5.12/31 10.0.5.14/31	WEKA Servers subnet: 10.10.2.0/24	0:15 1:20007 21001:26000 Except for 10.0.4.0/32 (0:15 3:20007 21001:26000)
frontend-spine2	*frontend-ai-leaf*	Loopbacks: 10.0.3.1/32 10.0.4.0/32 Leaf-spines links: 10.0.5.4/31 10.0.5.6/31 10.0.5.8/31 10.0.5.10/31 10.0.5.12/31 10.0.5.14/31	WEKA Servers subnet: 10.10.2.0/24	0:15 2:20007 21001:26000 Except for 10.0.4.0/32 (0:15 3:20007 21001:26000)

On the Spine nodes, BGP policies are configured by Apstra to advertise the following routes to the *frontend-weka-leaf* 1 leaf node:

- spine node own loopback interface address
- frontend-ai-leaf1 loopback interface address
- spine to frontend-ai-leaf1 nodes interfaces subnets

- GPU servers to frontend-ai-leaf1 node link subnets

Figure 123: Frontend Spine to Frontend Leaf for WEKA Storage Headend Server BGP

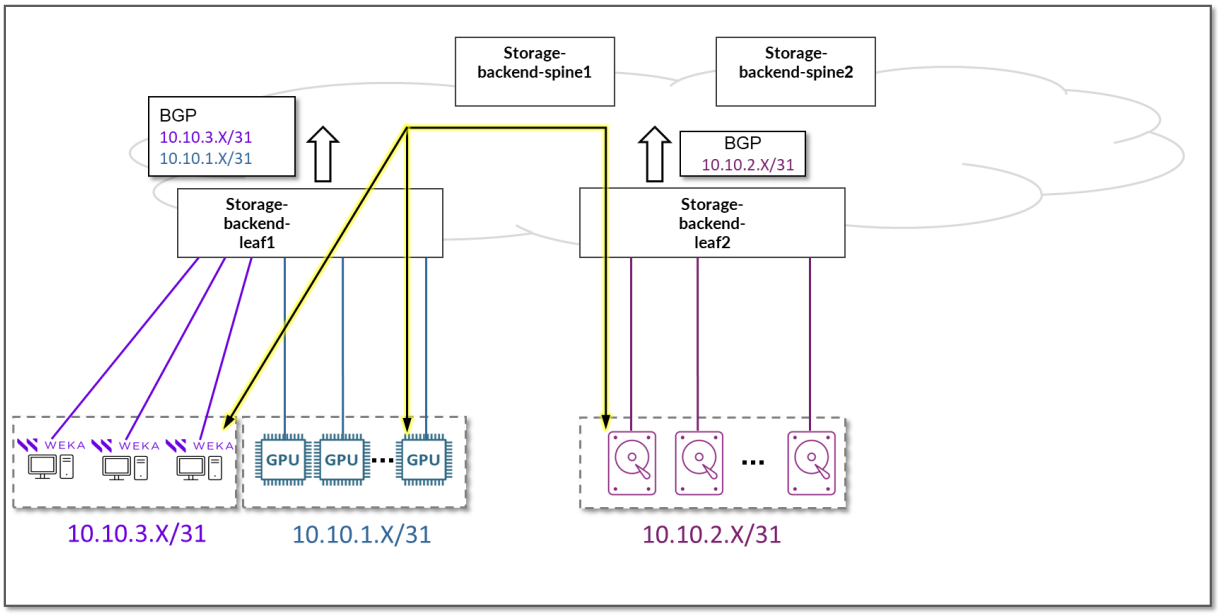
(Continued)

Leaf Node	Peer(s)	Advertised Routes		BGP Communities
frontend-spine2	*frontend-ai-leaf*	Loopbacks: 10.0.3.1/32 10.0.4.1/32 Leaf-spines links: 10.0.5.0/31 10.0.5.2/31 10.0.5.8/31 10.0.5.10/31 10.0.5.12/31 10.0.5.14/31	GPU servers <=> frontend spine links: 10.10.1.16/31 10.10.1.18/31 10.10.1.20/31 10.10.1.22/31 10.10.1.0/31 10.10.1.2/31 10.10.1.4/31 10.10.1.6/31 10.10.1.8/31 10.10.1.10/31 10.10.1.12/31 10.10.1.14/31 WEKA Management server's subnet: 10.10.3.0/24	0:15 2:20007 21001:26000 Except for 10.0.4.1/32 (0:15 4:20007 21001:26000)

By advertising the subnet assigned to the links between the leaf nodes and the GPU/storage servers, communication between GPUs and the WEKA storage and WEKA management servers is possible across the fabric.

Figure 125: GPU Server to WEKA storage and WEKA Management Servers



All the devices are configured to perform ECMP load balancing, as explained later in the document.

GPU Backend Network Connectivity

The GPU Backend fabric is designed as a Layer 3 IP Fabric, where the links between the leaf and spine nodes are configured with /31 IP addresses and are running EBGP. The fabric consists of 2 spine nodes, and 8 spine nodes (per stripe).

There is a single 400GE link between each leaf node and the spine nodes.

Figure 126: GPU Backend Spine to GPU Backend Leaf Nodes Connectivity

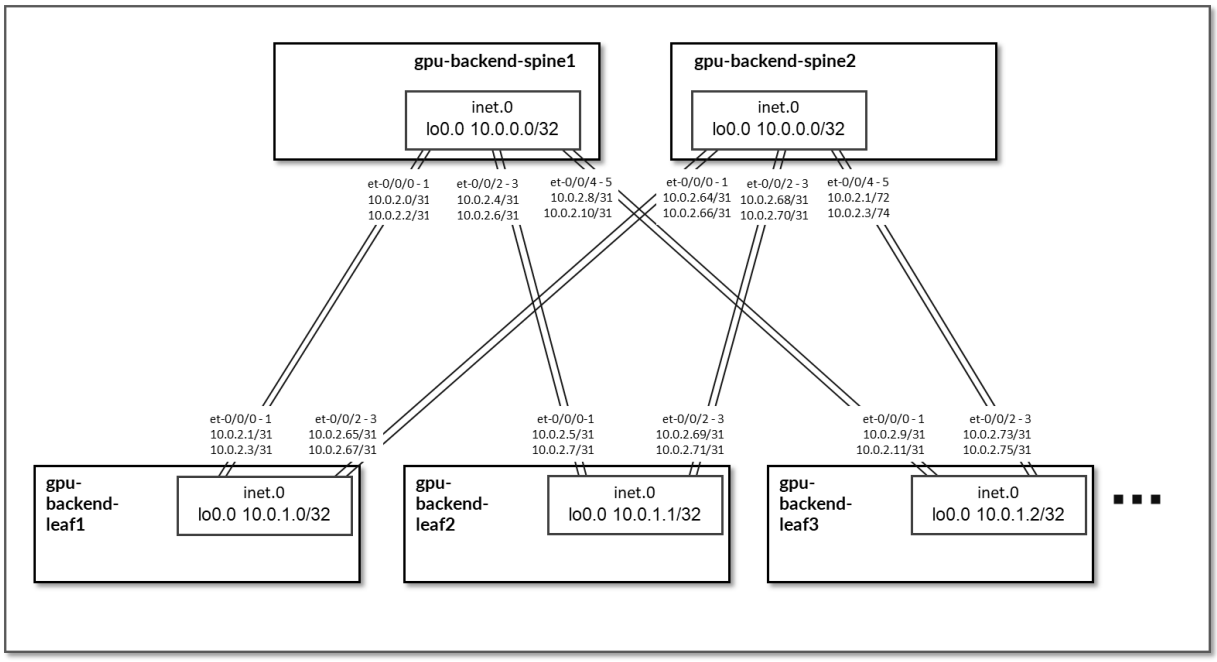


Table 40: GPU Backend Interface Addresses

Stripe #	Spine node	Leaf node	Spine IP address	Leaf IP address
1	*gpu-backend-spine* 1	*gpu-backend-leaf1*	10.0.2.0/31 10.0.2.2/31	10.0.2.1/31 10.0.2.3/31
1	*gpu-backend-spine* 1	*gpu-backend-leaf2*	10.0.2.4/31 10.0.2.6/31	10.0.2.5/31 10.0.2.7/31
1	*gpu-backend-spine* 1	*gpu-backend-leaf3*	10.0.2.8/31 10.0.2.10/31	10.0.2.9/31 10.0.2.11/31
. . .				

(Continued)

Stripe #	Spine node	Leaf node	Spine IP address	Leaf IP address
1	*gpu-backend-spine* 2	*gpu-backend-leaf1*	10.0.2.64/31 10.0.2.66/31	10.0.2.65/31 10.0.2.67/31
1	*gpu-backend-spine* 2	*gpu-backend-leaf2*	10.0.2.68/31 10.0.2.70/31	10.0.2.69/31 10.0.2.71/31
1	*gpu-backend-spine* 2	*gpu-backend-leaf3*	10.0.2.72/31 10.0.2.74/31	10.0.2.73/31 10.0.2.75/31

NOTE: all IP addresses are assigned by Apstra (from predefined pools of resources) based on the intent.

The loopback interfaces also have addresses automatically assigned by Apstra from a predefined pool.

Table 41: GPU Backend Loopback Addresses

Stripe #	Device	Loopback Interface Address
1	*gpu-backend-spine1*	10.0.0.0/32
1	*gpu-backend-spine2*	10.0.0.1/32
1	*gpu-backend-leaf1*	10.0.1.0/32
1	*gpu-backend-leaf2*	10.0.1.1/32
1	*gpu-backend-leaf3*	10.0.1.2/32

Each leaf node is assigned a /24 subnet out of 10.200/16 and a unique VLAN ID to provide connectivity to the GPU servers. Layer 3 connectivity is provided via an irb interface with an address out of the specific IP subnet, as shown in the table below.

Because each leaf node represents a rail, where all the GPUs with a given number connect, each rail in the cluster is mapped to a different /24 IP subnet.

Figure 127: GPU Backend Servers to Leaf Nodes Connectivity

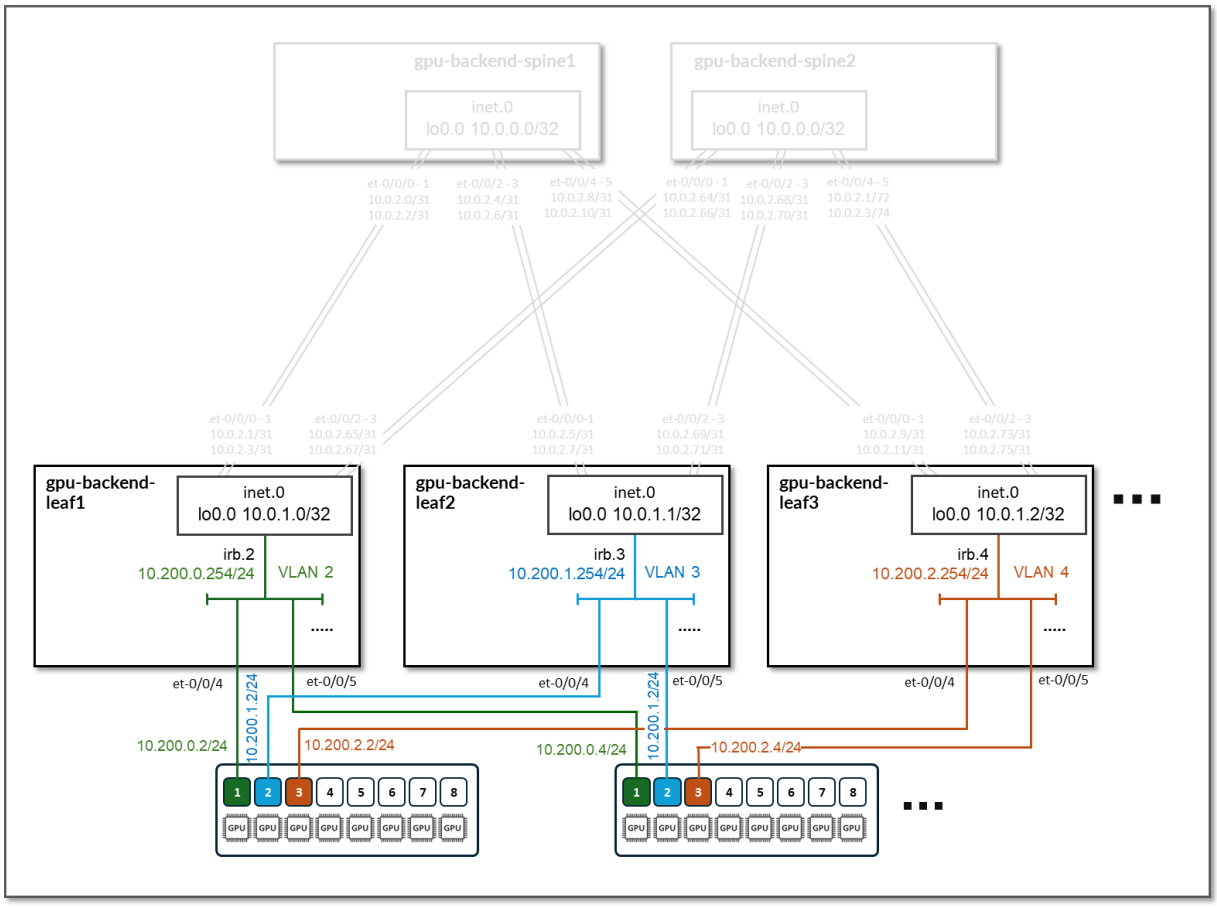

Table 128: GPU Backend Servers to Leaf Nodes Connectivity

Stripe #	Device	Rail #	VLAN #	Subnet	IRB on leaf	Connected device(s)
1	*gpu-backend-leaf* 1	1	2	10.200.0.0/24	10.200.0.254	GPU 1 from all 8 GPU servers
1	*gpu-backend-leaf* 2	2	3	10.200.1.0/24	10.200.1.254	GPU 2 from all 8 GPU servers
1	*gpu-backend-leaf* 3	3	4	10.200.2.0/24	10.200.2.254	GPU 3 from all 8 GPU servers

1	*gpu-backend-spine2*	*gpu-backend-leaf3*		4201032202	10.0.2.72/31 10.0.2.74/31	10.0.2.73/31 10.0.2.75/31
	. . .					

All the Autonomous System and community values are assigned by Apstra (from predefined pools of resources) based on the intent.

On the Leaf nodes, BGP policies are configured by Apstra to advertise the following routes to the spine nodes:

- Leaf node own loopback interface address
- leaf to spine interfaces subnets and
- irb interface subnet

Figure 130: GPU Backend Leaf Node BGP

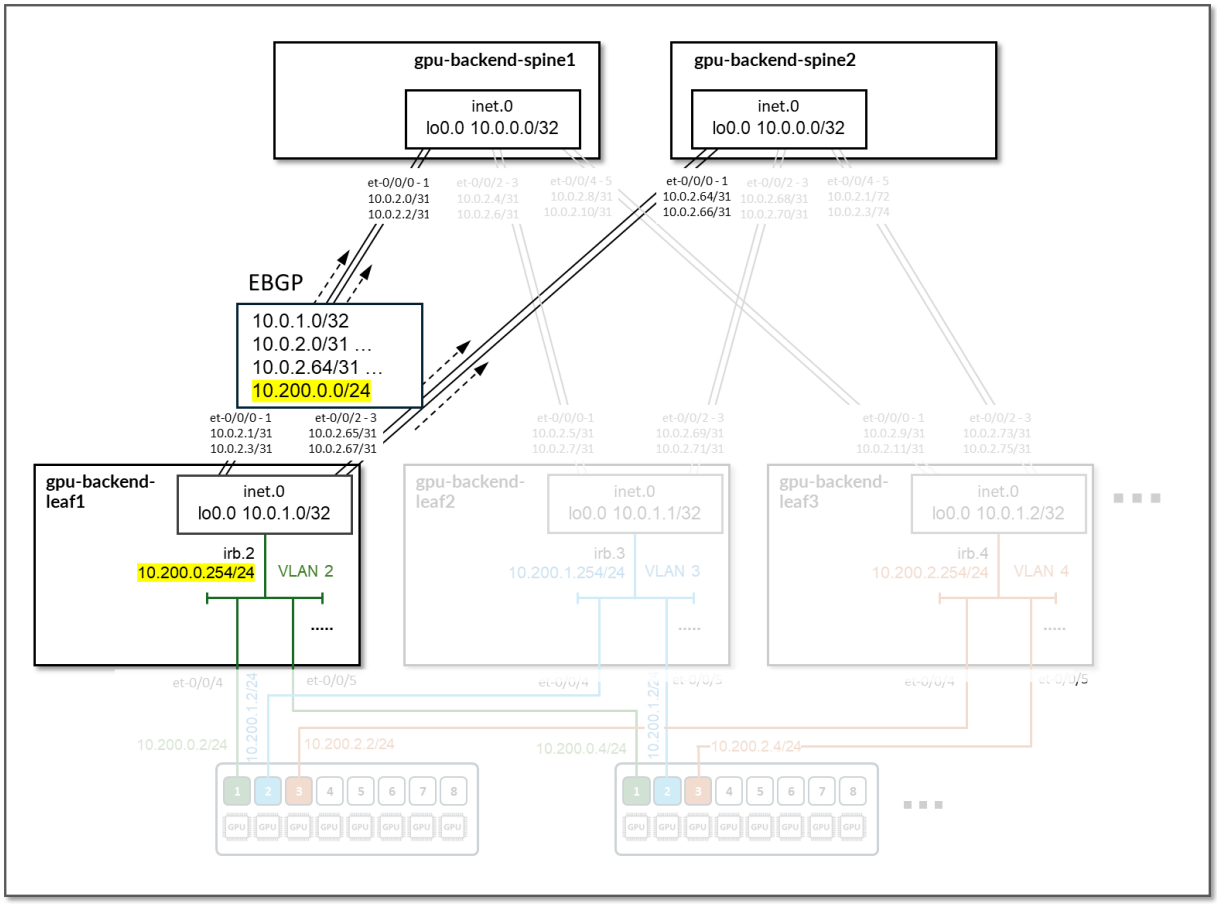

Table 44: GPU Backend Leaf Node Advertised Routes

Stripe #	Device	Advertised routes	BGP community
1	*gpu-backend-leaf* 1	10.0.1.0/32 10.0.2.0/31 10.0.2.64/31 10.200.0.0/24	3:20007 21001:26000
1	*gpu-backend-leaf* 2	10.0.1.1/32 10.0.2.4/31 10.0.2.68/31 10.200.1.0/24	4:20007 21001:26000
1	*gpu-backend-leaf* 3	10.0.1.2/32 10.0.2.8/31 10.0.2.72/31 10.200.2.0/24	5:20007 21001:26000

On the Spine nodes, BGP policies are configured by Apstra to advertise the following routes to the leaf nodes:

- spine node own loopback interface address
- leaf nodes' loopback interface address
- spine to leaf interfaces subnets
- irb interface subnet, as shown below:

Figure 131: GPU Backend Spine Node BGP

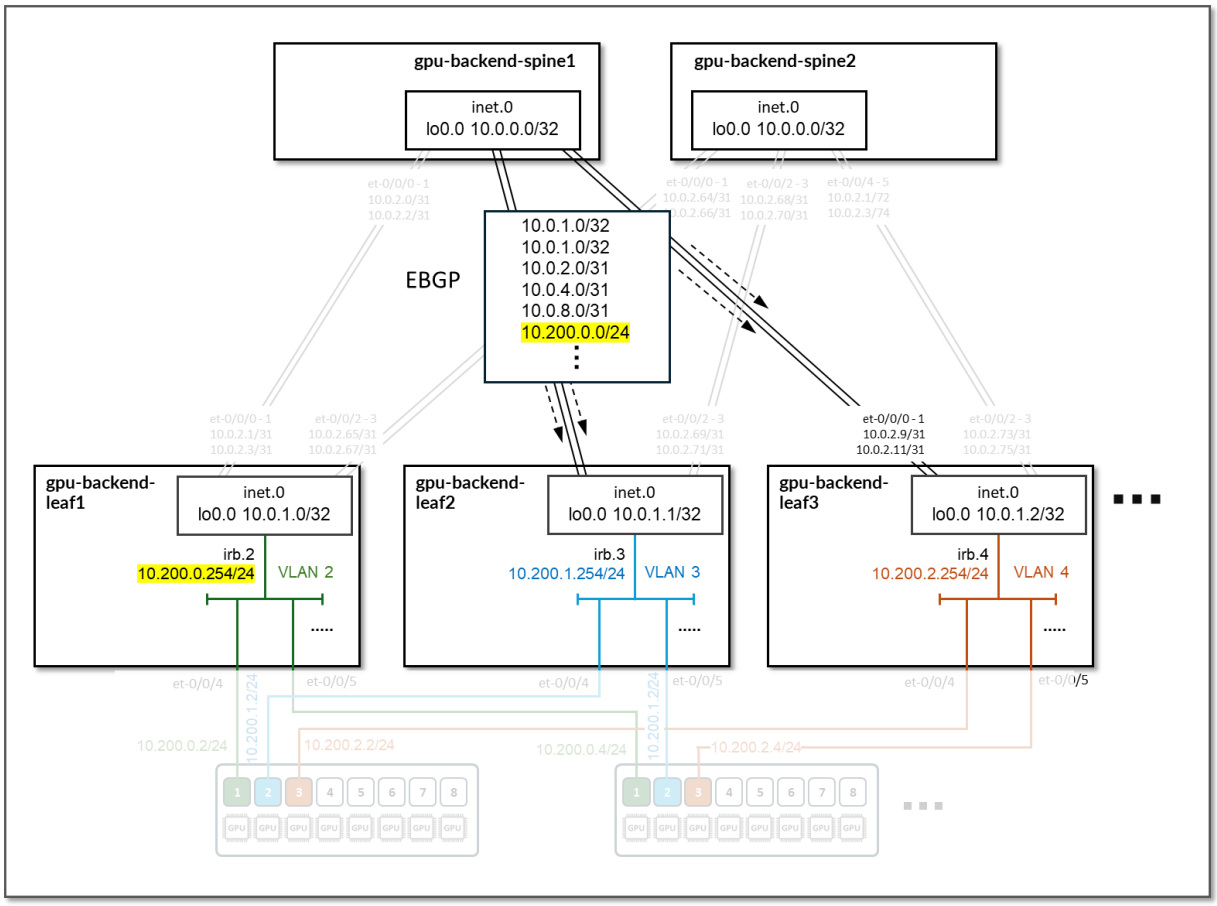

Table 45: GPU Backend Spine Node Advertised Routes

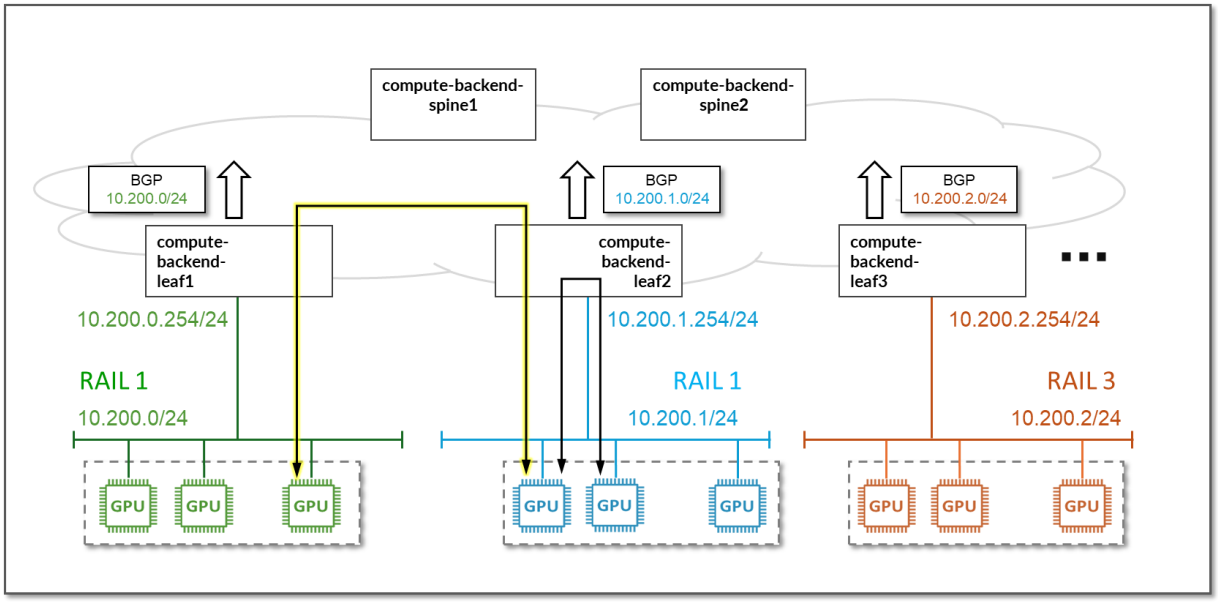
Stripe #	Spine Node	Advertised Routes	BGP Community
1	*gpu-backend-spine* 1	10.0.0.0/32 10.0.2.0/31 10.0.2.4/31 ... 10.200.1.0/24 ...	0:15 X:20007 21001:26000
1	*gpu-backend-spine* 2	10.0.0.1/32 10.0.2.64/31 10.0.2.68/31 ... 10.200.1.0/24 ...	0:15 X:20007 21001:26000

By advertising the irb interfaces subnet, communication between GPUs in different rails is possible across the fabric.

Figure 132: Communication Across Rails



All the devices are configured to perform ECMP load balancing, as explained later in the document.

Storage Backend Network Connectivity

The Storage Backend fabric is designed as a Layer 3 IP Fabric, where the links between the leaf and spine nodes are configured with /31 IP addresses as shown in the table below. The fabric consists of 2 spine nodes and 4 leaf nodes, where 2 leaf nodes are used to connect to the storage servers (named ***storage-backend-weka-leaf #)*** and 2 are used to connect to the GPU servers (named ***storage-backend-gpu-leaf #).***

There are three 400GE links between each ***storage-backend-weka-leaf #*** node and the spine nodes and two 400GE links between each ***storage-backend-gpu-leaf #*** node and the spine nodes as shown in Figure 133.

Figure 133: Storage Backend Spine to Storage Backend GPU Leaf Nodes Connectivity

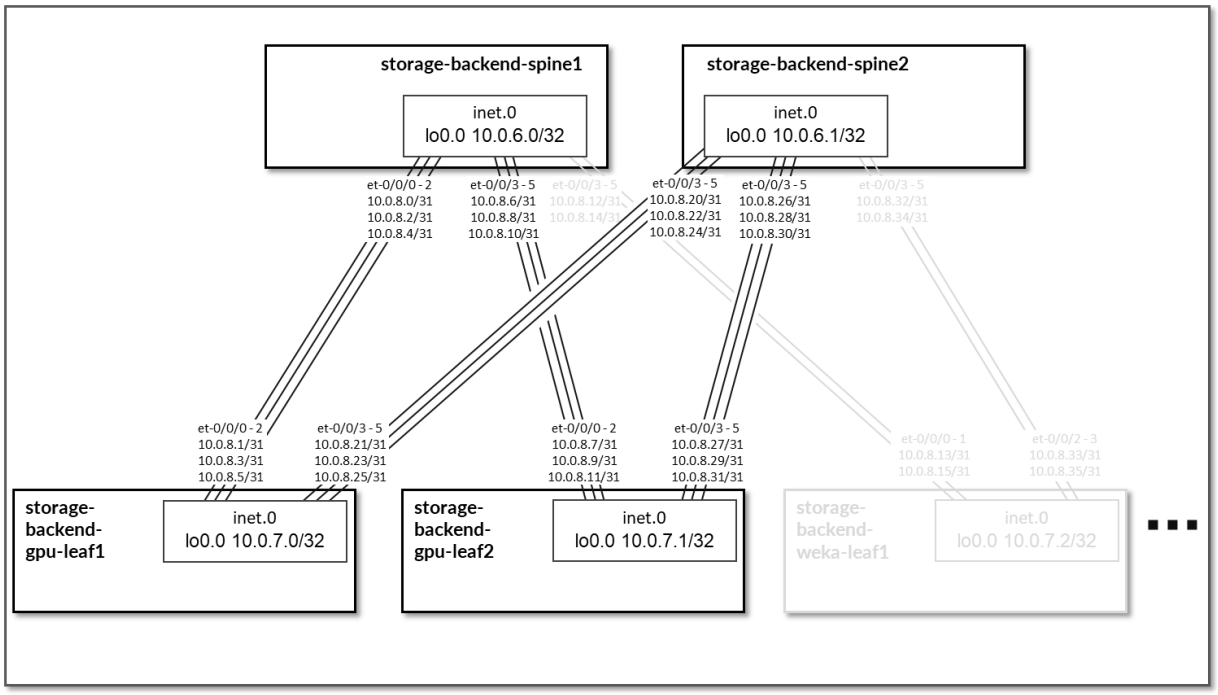


Figure 134: Storage Backend Spine to Storage Backend WEKA Storage Leaf Nodes Connectivity

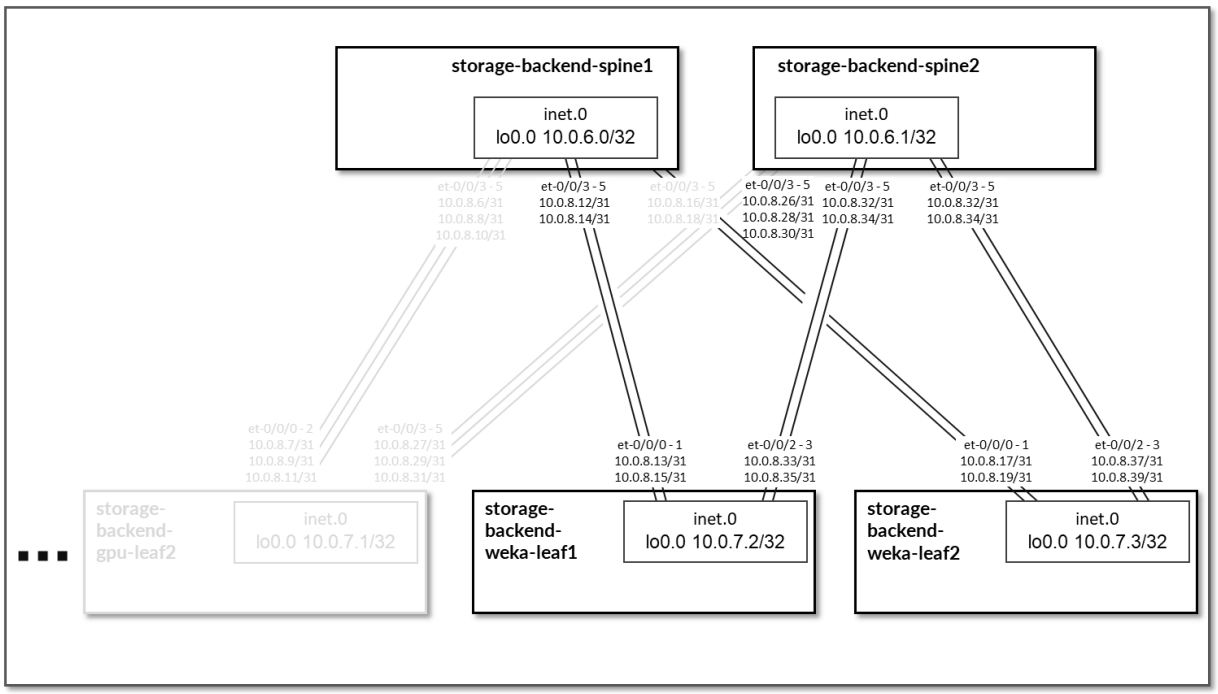

Table 46: Storage Backend Interface Addresses

Spine node	Leaf node	Spine IP Address	Leaf IP Address
storage-backend-spine 1	*storage-backend-gpu-leaf* 1	10.0.8.0/31 10.0.8.2/31 10.0.8.4/31	10.0.8.1/31 10.0.8.3/31 10.0.8.5/31

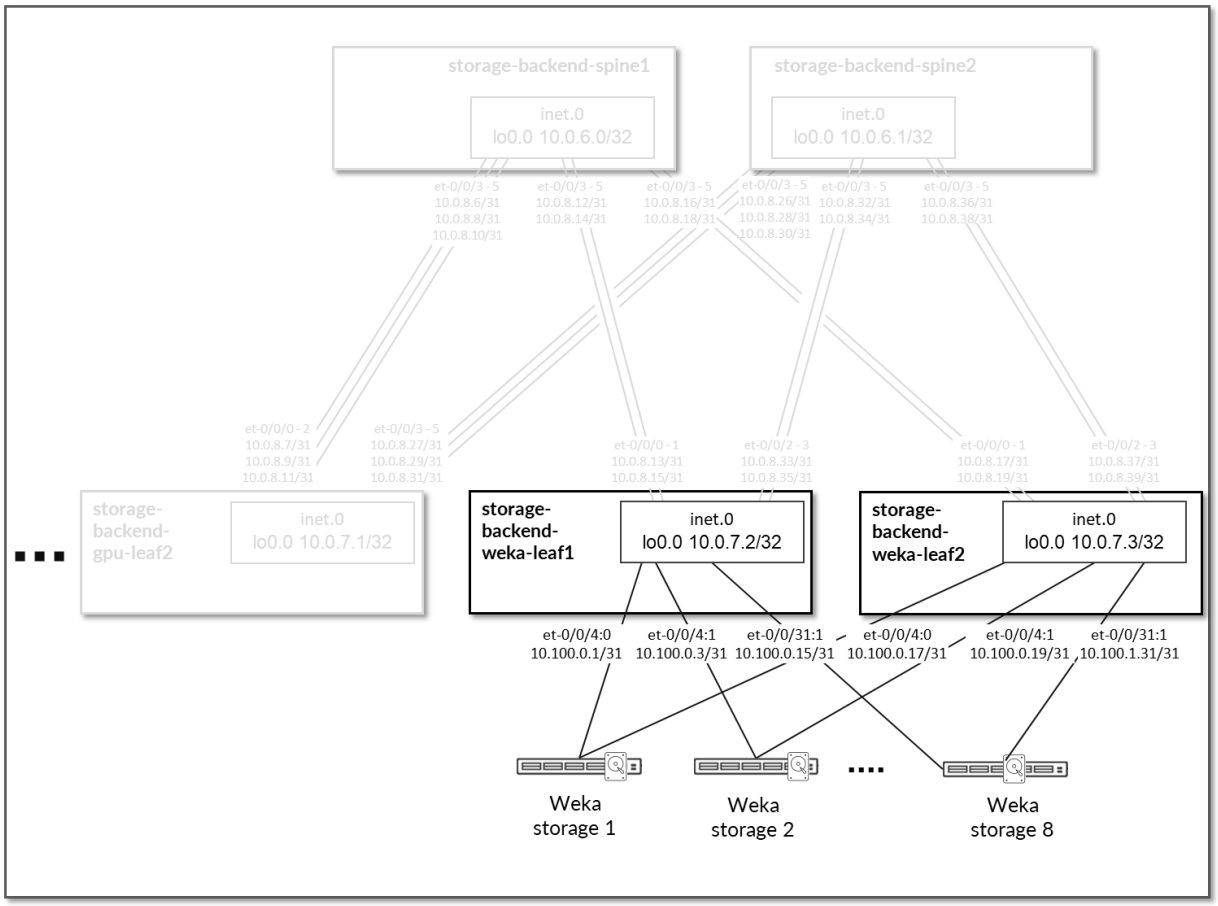
A100 GPU Server 6	*storage-backend-gpu-leaf* 2	10.100.2.2/31	10.100.2.3/31
A100 GPU Server 7	*storage-backend-gpu-leaf* 2	10.100.2.4/31	10.100.2.5/31
A100 GPU Server 8	*storage-backend-gpu-leaf* 2	10.100.2.6/31	10.100.2.7/31

Like the GPU servers, the WEKA storage servers are connected to the two ***storage-backend-weka-leaf #*** nodes as shown in Figure 136.

Figure 136: WEKA Storage servers to Leaf Nodes Connectivity



Each GPU server to leaf node connection is assigned to a /31 subnet out of 10.100.0.0/24, as shown in the following table.

Table 50: WEKA Storage Servers to Leaf Nodes Interface Addresses

WEKA Server	Leaf Node	WEKA Server IP Address	Leaf IP Address
WEKA storage Server 1	*storage-backend-weka-leaf* 1	10.100.0.0/31	10.100.0.1/31
WEKA storage Server 2	*storage-backend-weka-leaf* 1	10.100.0.2/31	10.100.0.3/31
WEKA storage Server 3	*storage-backend-weka-leaf* 1	10.100.0.4/31	10.100.0.5/31
WEKA storage Server 4	*storage-backend-weka-leaf* 1	10.100.0.5/31	10.100.0.7/31

(Continued)

WEKA Server	Leaf Node	WEKA Server IP Address	Leaf IP Address
WEKA storage Server 5	*storage-backend-weka-leaf* 1	10.100.0.8/31	10.100.0.9/31
WEKA storage Server 6	*storage-backend-weka-leaf* 1	10.100.0.10/31	10.100.0.11/31
WEKA storage Server 7	*storage-backend-weka-leaf* 1	10.100.0.12/31	10.100.0.13/31
WEKA storage Server 8	*storage-backend-weka-leaf* 1	10.100.0.14/31	10.100.0.15/31
WEKA storage Server 1	*storage-backend-weka-leaf* 2	10.100.0.16/31	10.100.0.17/31
WEKA storage Server 2	*storage-backend-weka-leaf* 2	10.100.0.18/31	10.100.0.19/31
WEKA storage Server 3	*storage-backend-weka-leaf* 2	10.100.0.20/31	10.100.0.21/31
WEKA storage Server 4	*storage-backend-weka-leaf* 2	10.100.0.22/31	10.100.0.23/31
WEKA storage Server 5	*storage-backend-weka-leaf* 2	10.100.0.24/31	10.100.0.25/31
WEKA storage Server 6	*storage-backend-weka-leaf* 2	10.100.0.26/31	10.100.0.27/31
WEKA storage Server 7	*storage-backend-weka-leaf* 2	10.100.0.28/31	10.100.0.29/31
WEKA storage Server 8	*storage-backend-weka-leaf* 2	10.100.0.30/31	10.100.0.31/31

Notice that the leaf nodes in this case are using physical interfaces to connect to the storage servers. Thus, no irb interface or vlan id are used for this connectivity.

EBGP is configured between the IP addresses assigned to the links between the spine and the leaf nodes as shown in Figure 93.

There will be 3 EBGP sessions between each ***storage-backend-weka-leaf #*** node and the spine nodes. Similarly, there will be 2 EBGP sessions between each ***storage-backend-gpu-leaf #*** node.

NOTE: all the Autonomous System and community values are assigned by Apstra (from predefined pools of resources) based on the intent.

On the Leaf nodes BGP policies are configured by Apstra to advertise the following routes to the spine nodes:

- Leaf node own loopback interface address,
- leaf to spine interfaces subnets and
- GPU/WEKA storage server to leaf node link subnets.

Figure 139: Storage Backend Leaf BGP

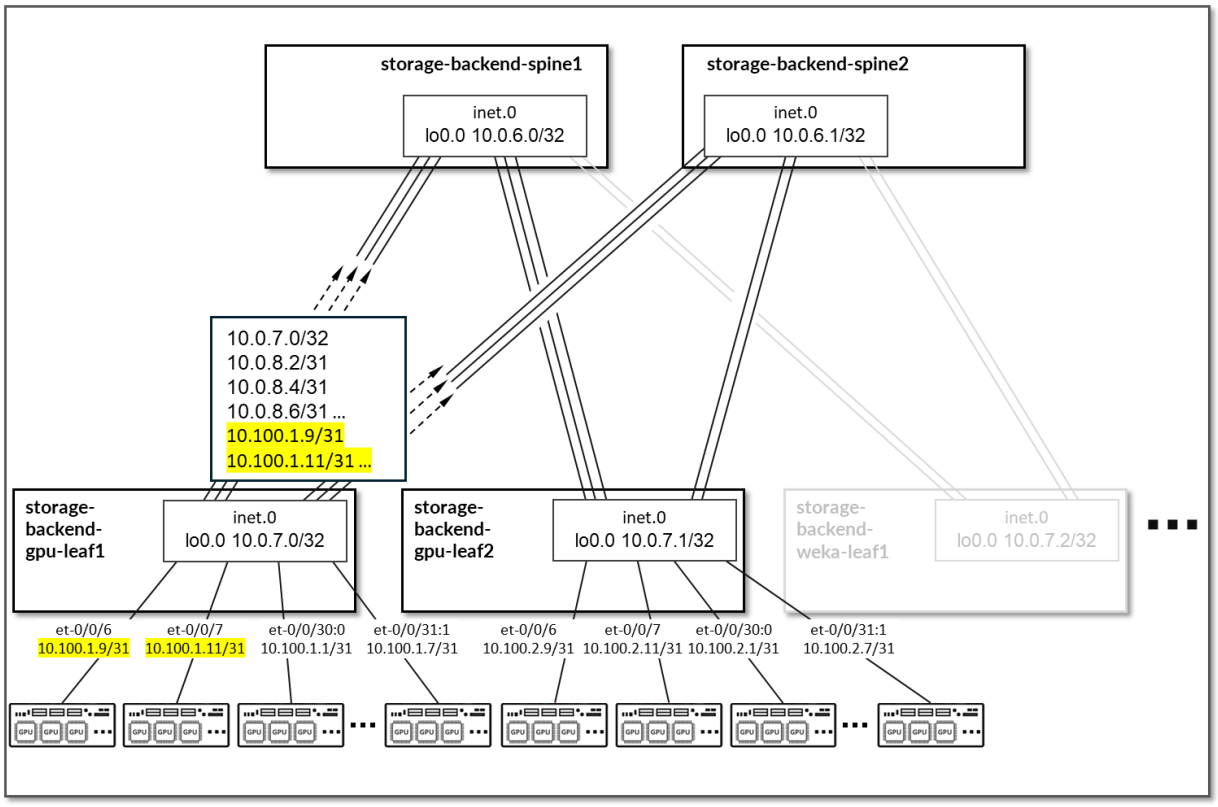

Table 52: Storage Backend Leaf Node Advertised Routes

Leaf Node	Peer	Advertised Routes		BGP Communities
storage-backend-gpu-leaf1	*storage-backend-spine1 &* *storage-backend-spine2*	10.0.7.0/32 10.0.8.0/31 10.0.8.2/31 10.0.8.4/31 10.0.8.20/31 ...	10.100.1.0/31 10.100.1.2/31 ...	3:20007 21001:26000
storage-backend-gpu-leaf2	*storage-backend-spine1 &* *storage-backend-spine2*	10.0.7.1/32 10.0.8.6/31 10.0.8.8/31 10.0.8.10/31 10.0.8.26/31 ...	10.100.2.0/31 10.100.2.2/31 ...	4:20007 21001:26000

(Continued)

Leaf Node	Peer	Advertised Routes		BGP Communities
storage-backend-weka-leaf1	*storage-backend-spine1 &* *storage-backend-spine2*	10.0.7.2/32 10.0.8.12/31 10.0.8.14/31 10.0.8.32/31 …	10.100.0.16/31 10.100.0.18/31 …	5:20007 21001:26000
storage-backend-weka-leaf2	*storage-backend-spine1 &* *storage-backend-spine2*	10.0.7.3/32 10.0.8.16/31 10.0.8.17/31 10.0.8.36/31 …	10.100.0.16/31 10.100.0.18/31 …	6:20007 21001:26000

On the Spine nodes, BGP policies are configured by Apstra to advertise the following routes to the leaf nodes:

- spine node own loopback interface address
- leaf nodes' loopback interface address
- spine to leaf interfaces subnets
- GPU/WEKA storage server to leaf node link subnets.

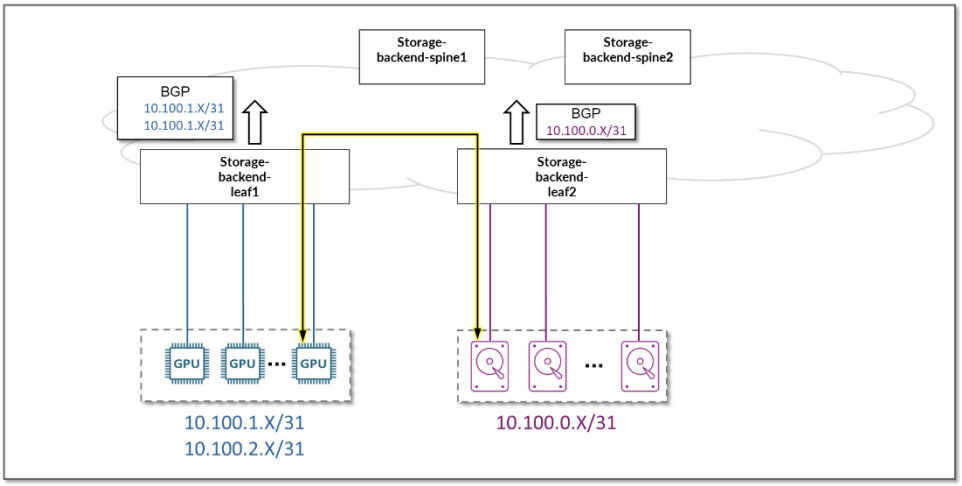
By advertising the subnet assigned to the links between the leaf nodes and the GPU/storage servers, communication between GPUs and the storage servers is possible across the fabric.

Figure 141: Storage Subnet Advertisement



NOTE: All the devices are configured to perform ECMP load balancing, as explained later in the document.

JVD Validation Framework

IN THIS SECTION

Platforms / Devices Under Test (DUT) on this JVD

To review the software versions and platforms on which this JVD was validated by Juniper Networks, see the Validated Platforms and Software section in this document.

JVD Validation Goals and Scope

IN THIS SECTION

Test Objectives

The primary objectives of the JVD testing can be summarized as:

- Qualification of the complete AI fabric design functionality including the Frontend, GPU Backend, and Storage Backend fabrics, and connectivity between NVIDIA GPUs and WEKA Storage.
- Qualification of the deployment steps based on Juniper Apstra.
- Ensure the design is well-documented and will produce a reliable, predictable deployment for the customer.

The qualification objectives included validating:

- Validation of blueprint deployment, device upgrade, incremental configuration pushes/provisioning, Telemetry/Analytics checking, failure mode analysis, congestion avoidance and mitigation, and verification of host, storage, and GPU traffic.

Test Goals

The AI JVD testing for the described network included the following:

- Design and blueprint deployment through Apstra of three distinct fabrics
- Fabric operation and monitoring through Apstra analytics and telemetry dashboard
- Congestion management with PFC and ECN, including failure scenarios
- End-to-end traffic flow, with Dynamic Load Balancing
- System health, ARP, ND, MAC, BGP (route, next hop), interface traffic counters, and so on

- Software operation verification (no anomalies, or issues found)
- AI fabric with Juniper Apstra successfully performing under the following required scenarios (must):
  - Node failure (reboot)
  - Interface failures (interface down/up, Laser on/off):

Under these scenarios the following were evaluated/validated:

- Completion of AI Job models within MLCommons Training benchmarks
- Traffic recovery was validated after all failure scenarios.
- impact to the fabric and check anomalies reporting in Apstra.

Other features tested:

- Mellanox Connect-X NIC card default settings.
- DSCP and CNP configuration on the NICs
- Connectivity between fabric-connected hosts created by Apstra towards NSX-managed hosts.
- BERT/DLRM test completion times
- Llama2 Inference against existing infrastructure.
- Thor2 5m DAC compatibility with QFX5240 switch (Thomahawk5)

Refer to the test report for more information.

Validated Devices Summary

The following devices were validated for the different roles and fabrics that comprise the AI cluster.

DEVICE	FRONTEND FABRIC		GPU BACKEND FABRIC			STORAGE FABRIC	
LEAF	SPINE	LEAF	LEAF	SPINE	Maximum # of GPUs per stripe	LEAF	SPINE
QFX5130-32CD	X	X				X	X

(Continued)

DEVICE	FRONTEND FABRIC		GPU BACKEND FABRIC			STORAGE FABRIC	
QFX5220-32CD	X	X	X		128 GPUs	X	X
QFX5230-32CD			X		128 GPUs	X	X
QFX5230-64CD			X	X	256 GPUs	X	X
QFX5240-64OD			X	X	256 GPUs	X	X
QFX5241-64OD			X	X	512 GPUs	X	X
PTX10008 LC1201				X			
PTX10008 LC1301				X			

Validated Optics Summary

The following optics were validated for the different roles and fabrics that comprise the AI cluster.

Table 54: Frontend Fabric Optics

Part number	Optics Name	Device Role	Device Model	Interface/NIC type

JVD Validation Test Results Summary and Analysis

The Test Results Summary and Analysis can be found in the following document:

AI Data Center Network with Juniper Apstra, NVIDIA GPUs, and WEKA Storage —Juniper Validated Design (JVD) Test Report

For a detailed test results report, contact your Juniper representative.

Recommendations Summary

The AI Data Center Network with Juniper Apstra, NVIDIA GPUs, and WEKA Storage JVD follows an industry-standard dedicated IP Fabric design. Three distinct fabrics provide maximum efficiency while maintaining focus on AI model scale, expedited completion times, and rapid evolution with the advent of AI technologies.

To follow best practice recommendations:

- A minimum of 4 spines in each fabric is suggested.
- Follow a rail-optimized fabric and maintain a 1:1 subscription factor in the GPU backend fabric.
- Maintain a 1:1 subscription factor in the Storage backend fabric.
- Implement Advanced Load Balancing mechanism instead of traditional ECMP for optimal load distribution in the GPU Backend Fabric.
- Implement DCQCN (PFC and ECN) to ensure a lossless fabric in the GPU Backend Fabric.
- Configure DCQCN (PFC and ECN) parameters on the AMD servers and change the NCCL_SOCKET interface to be the management (frontend) interface.
- Configure DCQCN (PFC and ECN) parameters on the Nvidia servers and change the NCCL_SOCKET interface to be the management (frontend) interface.
- The minimum recommended Junos OS releases for this JVD are:
  - Junos OS Release 23.4R2-S3 is for the Juniper QFX5130-32CD
  - Junos OS Release 23.4X100-D20 for Juniper QFX5220-32CD
  - Junos OS Release 23.4X100-D20 for Juniper QFX5230-64CD
  - Junos OS Release 23.4X100-D31 for Juniper QFX5240-64CD
  - Junos OS Release 23.4X100-D42 for Juniper QFX5240-64OD/QD
  - Junos OS Release 23.4R2-S3 for Juniper PTX10008
  - Apstra 6.1

The Juniper hardware listed in the Juniper Hardware and Software Components section are the best-suited switch platforms regarding features, performance, and the roles specified in this JVD.

Revision History

Table 57: Revision History

Date	Version	Description
Feb Jan 2026	JVD-AICLUSTERDC-AIML-AMD-02-10	Added 5m DAC. Added PTX10008 LC1301 & ALB Updated Apstra version to 6.1 Updated QFX5240 Junos EVO version. Added feedback from AMD and from customers. Improved Architecture Section
Dec 2025	JVD-AICLUSTERDC-AIML-02-09	Added QFX5241, and GLB configuration. Update Rail Optimized Section.
December 2024	JVD-AICLUSTERDC-AIML-02-08	Added PTX as spine.
November 2024	JVD-AICLUSTERDC-AIML-02-05	Utilized Junos OS Evolved Release 23.4X100-D20 for the leaf and spine switches.
